Abstract

Intergenerational relations have received increased attention in the context of population aging and increased childcare provision by grandparents. However, few studies have investigated the psychological consequences of becoming a grandparent. For the Big Five personality traits, the transition to grandparenthood has been proposed as a developmental task in middle adulthood and old age that contributes to personality development through the adoption of a new role—in line with the social investment principle. In this preregistered study, we used nationally representative panel data from the Netherlands ($N = 520$) and the United States ($N = 2,239$) to analyze first-time grandparents' development of the Big Five and life satisfaction in terms of mean-level changes, interindividual differences in change, and rank-order stability. We tested gender, paid work, and grandchild care as moderators of change trajectories. To address confounding bias, we employed propensity score matching using two procedures: matching grandparents with parents and with nonparents to achieve balance in different sets of carefully selected covariates. Longitudinal multilevel models demonstrated relative stability in the Big Five and life satisfaction over the transition to grandparenthood, and no consistent moderation effects. The few small effects of grandparenthood on personality development did not replicate across samples. Contrary to expectations, we also found no consistent evidence of larger interindividual differences in change in grandparents compared to the controls or of lower rank-order stability. Our findings add to recent critical re-examinations of the social investment principle and are discussed in light of characteristics of grandparenthood that might moderate personality development.

Keywords: grandparenthood, Big Five, life satisfaction, development, propensity score matching

The Transition to Grandparenthood: No Consistent Evidence for Change in the Big Five Personality Traits and Life Satisfaction

Becoming a grandparent is an important life event for many people in midlife or old age (Infurna et al., 2020). At the same time, there is considerable heterogeneity in how intensely grandparents are involved in their grandchildren's lives and care (Meyer & Kandic, 2017). In an era of population aging, the time that grandparents are alive and in good health during grandparenthood is prolonged compared to previous generations (Bengtson, 2001; Leopold & Skopek, 2015; Margolis & Wright, 2017). In addition, grandparents fulfill an increased share of childcare responsibilities (Hayslip et al., 2019; Pilkauskas et al., 2020). Thus, intergenerational relations have received heightened attention from psychological and sociological research in recent years (Bengtson, 2001; Coall & Hertwig, 2011; Fingerman et al., 2020). In the research on personality development, the transition to grandparenthood has been posited as an important developmental task arising in old age (Hutteman et al., 2014). However, empirical research on the psychological consequences of grandparenthood still remains sparse. Testing hypotheses derived from neo-socioanalytic theory (Roberts & Wood, 2006) in a prospective matched control-group design (see Luhmann et al., 2014), we investigate whether the transition to grandparenthood affects the Big Five personality traits and life satisfaction using data from two nationally representative panel studies.

Personality Development in Middle Adulthood and Old Age

The life span perspective conceptualizes aging as a lifelong process of development and adaptation (Baltes et al., 2006). Research embedded in this perspective has found personality traits to be subject to change across the entire life span (Costa et al., 2019; Graham et al., 2020; Specht, 2017; Specht et al., 2014; for recent reviews, see Bleidorn et al., 2021; Roberts & Yoon, 2021). Although a majority of personality development takes place in adolescence and emerging adulthood (Bleidorn & Schwaba, 2017; Pusch et al.,

2019; Schwaba & Bleidorn, 2018), evidence has accumulated that personality traits also undergo changes in middle and old adulthood (e.g., Allemand et al., 2008; Damian et al., 2019; Kandler et al., 2015; Lucas & Donnellan, 2011; Möttus et al., 2012; Mueller et al., 2016; Seifert et al., 2021; Wagner et al., 2016; for a review, see Specht, 2017).

Here, we examine the Big Five personality traits—agreeableness, conscientiousness, extraversion, neuroticism, and openness to experience—which constitute a broad categorization of universal patterns of thought, affect, and behavior (John et al., 2008; John & Srivastava, 1999). Changes over time in the Big Five occur both in mean trait levels (i.e., mean-level change; Roberts et al., 2006) and in the ordering of people relative to each other on trait dimensions (i.e., rank-order stability; Anusic & Schimmack, 2016; Roberts & DelVecchio, 2000). A lack of observed changes in mean trait levels does not necessarily mean that individual trait levels are stable over time, and perfect rank-order stability does not preclude mean-level changes. Mean-level changes in early to middle adulthood (circa 30–60 years old; Hutteman et al., 2014) are typically characterized by greater maturity, as evidenced by increased agreeableness and conscientiousness and decreased neuroticism (Damian et al., 2019; Roberts et al., 2006). In old age (circa 60 years and older; Hutteman et al., 2014), research is generally more sparse, but there is some evidence of a *reversal* of the maturity effect following retirement (sometimes termed *la dolce vita* effect; Asselmann & Specht, 2021; Marsh et al., 2013; cf. Schwaba & Bleidorn, 2019) and at the end of life when health problems arise (Wagner et al., 2016).

In terms of rank-order stability, most prior studies have shown support for an inverted U-shape trajectory (Ardelt, 2000; Lucas & Donnellan, 2011; Seifert et al., 2021; Specht et al., 2011; Wortman et al., 2012): Rank-order stability rises until it reaches a plateau in midlife, and decreases in old age. However, evidence is mixed on whether rank-order stability actually decreases again in old age (see Costa et al., 2019; Wagner et al., 2019). Nonetheless, the previously held view that personality is stable or “set like plaster” (Specht, 2017, p. 64) after one reaches adulthood (or leaves emerging adulthood

99 behind; Bleidorn & Schwaba, 2017) has been largely abandoned (Specht et al., 2014).

100 Theories explaining the mechanisms of personality development in middle
101 adulthood and old age emphasize genetic influences and life experiences as interdependent
102 sources of stability and change (Bleidorn et al., 2021; Specht et al., 2014; Wagner et al.,
103 2020). We conceptualize the transition to grandparenthood as a life experience involving
104 the adoption of a new social role according to the social investment principle of
105 neo-socioanalytic theory (Lodi-Smith & Roberts, 2007; Roberts & Wood, 2006). The social
106 investment principle states that normative life events or transitions such as entering the
107 work force or becoming a parent lead to personality maturation through the adoption of
108 new social roles (Roberts et al., 2005). These new roles encourage or compel people to act
109 in a more agreeable, conscientious, and emotionally stable (i.e., less neurotic) way, and
110 people's experiences in these roles as well as societal expectations towards them are
111 hypothesized to drive long-term personality development (Lodi-Smith & Roberts, 2007;
112 Wrzus & Roberts, 2017). Conversely, consistent social roles foster personality stability.

113 The paradoxical theory of personality coherence (Caspi & Moffitt, 1993) offers a
114 complimentary perspective on personality development through role transitions: It assumes
115 that trait change is more likely whenever people transition into unknown environments
116 where pre-existing behavioral responses are no longer appropriate and social expectations
117 give clear indications how to behave instead. Environments that provide no clear guidance
118 on how to behave favor stability. The finding that age-graded, normative life experiences,
119 such as the transition to grandparenthood, drive personality development would therefore
120 also be in line with the paradoxical theory of personality coherence (see Specht et al., 2014).

121 Empirically, certain life events such as the first romantic relationship (Wagner et al.,
122 2015), the transition from high school to university, or the first job (Asselmann & Specht,
123 2021; Golle et al., 2019; Lüdtkke et al., 2011) have been found to co-occur with mean-level
124 changes that are (partly) consistent with the social investment principle (for a review, see
125 Bleidorn et al., 2018). However, recent findings on the transition to parenthood fail to

support the social investment principle (Asselmann & Specht, 2020b; van Scheppingen et al., 2016). An analysis of trajectories of the Big Five before and after eight life events produced limited support for the social investment principle: Small increases in emotional stability occurred following the transition to employment but not in the other traits or following the other life events theoretically linked to social investment (Denissen et al., 2019).

Overall, much remains unknown about the environmental factors that underlie personality development in middle adulthood and old age. Recent research on retirement offers an indication that age-graded, normative life experiences contribute to change following a period of relative stability in midlife (Bleidorn & Schwaba, 2018; Schwaba & Bleidorn, 2019). These results are only partly in line with the social investment principle in terms of mean-level changes and display substantial interindividual differences in change trajectories. Schwaba and Bleidorn described retirement as a “divestment” of social roles (2019, p. 660) that functions differently than *social investment*, which adds a role (another paper introduced the term *personality relaxation* in this context; see Asselmann & Specht, 2021). Grandparenthood could represent a psychological investment in a new role in middle adulthood and old age—given that grandparents have regular contact with their grandchild and actively take part in childcare (Lodi-Smith & Roberts, 2007).

Grandparenthood

The transition to grandparenthood can be described as a time-discrete life event marking the beginning of one’s status as a grandparent (Luhmann et al., 2012). In terms of characteristics of major life events (Luhmann et al., 2020), the transition to grandparenthood stands out in that it is externally caused (by one’s children; see also Arpino, Gumà, et al., 2018; Margolis & Verdery, 2019), but also predictable as soon as children reveal their family planning or pregnancy. The transition to grandparenthood has been labeled a countertransition due to this lack of direct control over its timing (Hagestad

152 & Neugarten, 1985; as cited in Arpino, Gumà, et al., 2018). Grandparenthood is also
153 generally positive in valence and emotionally significant if the grandparent maintains a
154 good relationship with their child.

155 Grandparenthood can be characterized as a developmental task (Hutteman et al.,
156 2014) that generally takes place in (early) old age, although this varies considerably both
157 within and between cultures (Leopold & Skopek, 2015; Skopek & Leopold, 2017). Still, the
158 period in which parents experience the birth of their first grandchild coincides with the end
159 of (relative) personality stability in midlife (Specht, 2017), when retirement, shifting social
160 roles, and initial cognitive and health declines can disrupt life circumstances, setting
161 processes of personality development in motion (e.g., Mueller et al., 2016; Stephan et al.,
162 2014). As a developmental task, grandparenthood is considered part of a normative
163 sequence of aging that is subject to societal expectations and values that differ across
164 cultures and historical time (Baltes et al., 2006; Hutteman et al., 2014). Mastering
165 developmental tasks (i.e., fulfilling roles and expectations) is hypothesized to drive
166 personality development towards maturation similarly to propositions of the social
167 investment principle, that is, leading to higher levels of agreeableness and
168 conscientiousness, and lower levels of neuroticism (Roberts et al., 2005; Roberts & Wood,
169 2006). Grandparent's investments in their grandchildren have been discussed as beneficial
170 in terms of the evolutionary, economic, and sociological advantages they provide for the
171 intergenerational family structure (Coall et al., 2018; Coall & Hertwig, 2011).

172 In comparison to the transition to parenthood, which has been found to be
173 ambivalent in terms of both personality maturation and life satisfaction (Aassve et al.,
174 2021; Johnson & Rodgers, 2006; Krämer & Rodgers, 2020; van Scheppingen et al., 2016),
175 Hutteman et al. (2014) hypothesize that the transition to grandparenthood is positive
176 because it (usually) does not impose the stressful demands of daily childcare on
177 grandparents. However, societal expectations about how grandparents should behave are
178 less clearly defined than expectations around parenthood, and depend heavily on the

179 degree of possible grandparental investment (Lodi-Smith & Roberts, 2007)—how close
180 grandparents live to their children, the quality of their relationship, and sociodemographic
181 factors that create conflicting role demands (Bordone et al., 2017; Lumsdaine & Vermeer,
182 2015; Silverstein & Marenco, 2001; cf. Muller & Litwin, 2011). In the entire population of
183 first-time grandparents, this diversity of role investments might generate pronounced
184 interindividual differences in intraindividual personality change.

185 While we could not find prior studies investigating the development of the Big Five
186 over the transition to grandparenthood, there is some evidence of changes in life
187 satisfaction across the transition to grandparenthood. In cross-sectional studies,
188 grandparents who provide grandchild care or have close relationships with their older
189 grandchildren often have higher life satisfaction (e.g., Mahne & Huxhold, 2014; Triadó et
190 al., 2014). There are a few longitudinal studies but they have produced conflicting
191 conclusions: Studies using data from the Survey of Health, Ageing and Retirement in
192 Europe (SHARE) showed that the birth of a grandchild was followed by improvements in
193 quality of life and life satisfaction, but only among women (Tanskanen et al., 2019) and
194 only in first-time grandmothers via their daughters (Di Gessa et al., 2019). Several studies
195 demonstrated that grandparents who were actively involved in childcare experienced larger
196 increases in life satisfaction (Arpino, Bordone, et al., 2018; Danielsbacka et al., 2019;
197 Danielsbacka & Tanskanen, 2016). On the other hand, fixed effects regression models¹
198 using SHARE data did not find any effects of first-time grandparenthood on life
199 satisfaction regardless of grandparental investment and only minor decreases in depressive
200 symptoms in grandmothers (Sheppard & Monden, 2019).

201 In a similar vein, some prospective studies have reported beneficial effects of the
202 transition to grandparenthood and of grandparental childcare investment on various health
203 measures, especially in women (Chung & Park, 2018; Condon et al., 2018; Di Gessa et al.,

¹ Fixed effects regression models rely exclusively on within-person variance (see Brüderl & Ludwig, 2015; McNeish & Kelley, 2019).

204 2016a, 2016b). Again, the beneficial effects of grandparenthood on self-rated health did not
205 persist in fixed effects analyses, such as Ates's (2017) analysis of longitudinal data from the
206 German Aging Survey (DEAS).

207 We are not aware of any study investigating trait rank-order stability over the
208 transition to grandparenthood. Other life events are associated with rank-order stability of
209 personality and well-being, although only certain events and traits (e.g., Denissen et al.,
210 2019; Hentschel et al., 2017; Specht et al., 2011). Altogether, evidence is lacking on the Big
211 Five and inconclusive on life satisfaction (and related measures) which might be due to
212 different methodological approaches that do not always account for confounding (i.e.,
213 selection effects).

214 **Methodological Considerations**

215 Effects of life events on psychological traits generally tend to be small and need to
216 be properly analyzed using robust, prospective designs and appropriate control groups
217 (Bleidorn et al., 2018; Luhmann et al., 2014). This is necessary because pre-existing
218 differences between prospective grandparents and non-grandparents in variables related to
219 the development of the Big Five or life satisfaction introduce confounding bias when
220 estimating the effects of the transition to grandparenthood (VanderWeele et al., 2020). The
221 impact of adjusting (or not adjusting) for pre-existing differences, or background
222 characteristics, was recently emphasized in the prediction of life outcomes from personality
223 in a mega-analytic framework of ten large panel studies (Beck & Jackson, 2021).

224 Propensity score matching is one technique to account for confounding bias by equating
225 groups in their estimated propensity to experience the event (Thoemmes & Kim, 2011).
226 This propensity is calculated from regressing the so-called treatment variable (indicating
227 whether someone experienced the event) on covariates related to the likelihood of
228 experiencing the event and to the outcomes. This approach addresses confounding bias by
229 creating balance between the groups in the covariates used to calculate the propensity

score (Stuart, 2010).

We adopt a prospective design that tests the effects of becoming first-time grandparents against two propensity-score-matched control groups separately: first, parents (but not grandparents) with at least one child of reproductive age, and, second, nonparents. Adopting two control groups allows us to disentangle potential effects attributable to becoming a grandparent from effects attributable to already being a parent (i.e., parents who eventually become grandparents might share additional similarities with parents who do not). Thus, we are able to address selection effects into grandparenthood more comprehensively than previous research and we cover the first two of three causal pathways to not experiencing grandparenthood pointed out in demographic research (Margolis & Verdery, 2019): childlessness, childlessness of one's children, and not living long enough to become a grandparent. Our comparative design controls for average age-related and historical trends in the Big Five traits and life satisfaction (Luhmann et al., 2014). The design also enables us to report effects of the transition to grandparenthood unconfounded by instrumentation effects, which describe the tendency of reporting lower well-being scores with each repeated measurement (Baird et al., 2010).

We improve upon previous longitudinal studies using matched control groups (e.g., Anusic et al., 2014a, 2014b; Yap et al., 2012) by matching at a specific time point before the transition to grandparenthood (i.e., at least two years beforehand) and not based on individual survey years. This design choice ensures that the covariates involved in the matching procedure are not already influenced by the event or anticipation of it (Greenland, 2003; Rosenbaum, 1984; VanderWeele, 2019; VanderWeele et al., 2020), thereby reducing the risk of introducing confounding through collider bias (Elwert & Winship, 2014). Similar approaches in the study of life events have been adopted in recent studies (Balbo & Arpino, 2016; Krämer & Rodgers, 2020; van Scheppingen & Leopold, 2020).

Current Study

In the current study, we examine the development of the Big Five personality traits across the transition to grandparenthood in a prospective, quasi-experimental design, thereby extending previous research on the effects of this transition on well-being to psychological development in a more general sense. We also revisit the development of life satisfaction, which we define as the general, cognitive appraisal of one's well-being in life based on subjective criteria (Eid & Larsen, 2008). Three research questions motivate the current study which—to our knowledge—is the first to analyze Big Five personality development over the transition to grandparenthood:

1. What are the effects of the transition to grandparenthood on mean-level trajectories of the Big Five traits and life satisfaction?
2. How large are interindividual differences in intraindividual change for the Big Five traits and life satisfaction over the transition to grandparenthood?
3. How does the transition to grandparenthood affect rank-order stability of the Big Five traits and life satisfaction?

To address these questions, we used two nationally representative panel data sets and compared grandparents' development over the transition to grandparenthood with that of matched respondents who did not become grandparents during the study period (Luhmann et al., 2014). Informed by the social investment principle and previous research on personality development in middle adulthood and old age, we preregistered the following hypotheses (see blinded file *Preregistration.pdf* on https://osf.io/75a4r/?view_only=ac929a2c41fb4afd9d1a64a3909848d0):

- H1a: Following the birth of their first grandchild, grandparents increase in agreeableness and conscientiousness, and decrease in neuroticism compared to the matched control groups of parents (but not grandparents) and nonparents. We do

not expect the groups to differ in their trajectories of extraversion and openness to experience.

- H1b: Grandparents' post-transition increases in agreeableness and conscientiousness, and decreases in neuroticism are more pronounced among those who provide substantial grandchild care.
- H1c: Grandmothers increase in life satisfaction following the transition to grandparenthood as compared to the matched control groups but grandfathers do not.
- H2: Individual differences in intraindividual change in the Big Five and life satisfaction are larger in the grandparent group than the control groups.
- H3: Compared to the matched control groups, grandparents' rank-order stability of the Big Five and life satisfaction over the transition to grandparenthood is smaller.

Finally, commitments to other institutions necessarily constrain the amount of possible grandparental investment. Thus, exploratorily, we probe the moderator *performing paid work*, which could constitute a potential role conflict among grandparents.

Methods

Samples

To evaluate these hypotheses, we used data from two population-representative panel studies: the Longitudinal Internet Studies for the Social Sciences (LISS) panel from the Netherlands, and the Health and Retirement Study (HRS) from the United States.

The LISS panel is a representative sample of the Dutch population initiated in 2008 with data collection still ongoing (Scherpenzeel, 2011; van der Laan, 2009). It is administered by Centerdata (Tilburg University). The survey population is a true probability sample of households drawn from the population register (Scherpenzeel & Das, 2010). While roughly half of invited households consented to participate, refresher samples were drawn to oversample previously underrepresented groups using information about response rates and their association with demographic variables (see

<https://www.lissdata.nl/about-panel/sample-and-recruitment/>). Data collection was carried out online, and respondents were provided the technical equipment if needed. We included yearly assessments from 2008 to 2020 as well as basic demographics assessed monthly. For later coding of covariates from these monthly demographic data we used the first available assessment in each year.

The HRS is an ongoing population-representative study of older adults in the United States (Sonnega et al., 2014) administered by the Survey Research Center (University of Michigan). Initiated in 1992 with a first cohort of individuals aged 51-61 and their spouses, the study has since been expanded through additional cohorts (see <https://hrs.isr.umich.edu/documentation/survey-design/>). In addition to the biennial in-person or telephone interview, since 2006 the study has included a leave-behind questionnaire covering psychosocial topics including the Big Five personality traits and life satisfaction. These topics, however, were only administered every four years starting in 2006 for one half of the sample and in 2008 for the other half. We included personality data from 2006 to 2018, all available data for the coding of the transition to grandparenthood from 1996 to 2018, as well as covariate data from 2006 to 2018 including variables drawn from the Imputations File and the Family Data (only available up to 2014).

These two panel studies provided the advantage that they contained several waves of personality data as well as information on grandparent status and a broad range of covariates. While the HRS provided a large sample with a wider age range, the LISS was smaller and younger but provided more frequent personality assessments spaced every one to two years. Included grandparents from the LISS were younger because grandparenthood questions were part of the Work and Schooling module and—for reasons unknown to us—filtered to respondents performing paid work. Thus, older, retired first-time grandparents from the LISS could not be identified. Even though we have published using the LISS and HRS data before (see preregistration, https://osf.io/75a4r/?view_only=ac929a2c41fb4afd9d1a64a3909848d0), these publications

do not overlap with the current study in the focus on grandparenthood.² The present study used de-identified archival data available in the public domain, which meant that it was not necessary to obtain ethical approval from an IRB.

Measures

Personality

In the LISS, the Big Five personality traits were assessed using the 50-item version of the IPIP Big Five Inventory scales (Goldberg, 1992). For each trait, respondents answered ten 5-point Likert-scale items (1 = *very inaccurate*, 2 = *moderately inaccurate*, 3 = *neither inaccurate nor accurate*, 4 = *moderately accurate*, 5 = *very accurate*). Example items included “like order” (conscientiousness), “sympathize with others’ feelings” (agreeableness), “worry about things” (neuroticism), “have a vivid imagination” (openness to experience), and “start conversations” (extraversion). In each wave, we took a respondent’s mean of each subscale as their trait score. Internal consistencies at the time of matching, as indicated by ω_h (McNeish, 2018), averaged $\omega_h = 0.70$ over all traits ($\omega_t = 0.89$; $\alpha = 0.83$; see Table S1). Other studies have shown measurement invariance for these scales across time and age groups, and convergent validity with the Big Five Inventory (BFI-2; Schwaba & Bleidorn, 2018; Denissen et al., 2020). The Big Five and life satisfaction were administered yearly but with planned missingness in some years for certain cohorts (see Denissen et al., 2019).

In the HRS, the Midlife Development Inventory (MIDI) scales measured the Big Five (Lachman & Weaver, 1997) with 26 adjectives (five each for conscientiousness, agreeableness, and extraversion; four for neuroticism; seven for openness to experience). Respondents were asked to rate on a 4-point scale how well each item described them (1 = *a lot*, 2 = *some*, 3 = *a little*, 4 = *not at all*). Example adjectives included “organized”

² Publications using LISS data can be searched at <https://www.dataarchive.lissdata.nl/publications/>. Publications using HRS data can be searched at <https://hrs.isr.umich.edu/publications/biblio/>.

(conscientiousness), “sympathetic” (agreeableness), “worrying” (neuroticism), “imaginative” (openness to experience), and “talkative” (extraversion). For better comparability with the LISS panel, we reverse-scored all items so that higher values corresponded to higher trait levels and, in each wave, took the mean of each subscale as the trait score. Big Five trait scores showed satisfactory internal consistencies at the time of matching that averaged $\omega_h = 0.63$ over all traits ($\omega_t = 0.80$; $\omega_h = 0.72$; see Table S1).

Life Satisfaction

In both samples, life satisfaction was assessed using the 5-item Satisfaction with Life Scale (SWLS; Diener et al., 1985) which respondents answered on a 7-point Likert scale (1 = *strongly disagree*, 2 = *somewhat disagree*, 3 = *slightly disagree*, 4 = *neither agree or disagree*, 5 = *slightly agree*, 6 = *somewhat agree*, 7 = *strongly agree*)³. An example item was “I am satisfied with my life”. Internal consistency at the time of matching was $\alpha = 0.91$ in the LISS with the parent control sample ($\alpha = 0.88$ with the nonparent control sample), and $\alpha = 0.90$ in the HRS with the parent control sample ($\alpha = 0.90$ with the nonparent control sample).

Transition to Grandparenthood

The procedure to obtain information on the transition to grandparenthood generally followed the same steps in both samples. This coding was based on items that differed slightly, however: In the LISS, respondents performing paid work were asked “Do you have children and/or grandchildren?” and were offered the answer categories “children”, “grandchildren”, and “no children or grandchildren”. In the HRS, all respondents were asked to state their total number of grandchildren: “Altogether, how many grandchildren do you (or your husband / wife / partner, or your late husband / wife / partner) have? Include as grandchildren any children of your (or your [late] husband’s / wife’s / partner’s)

³ In the LISS, the “somewhat” was omitted and instead of “or”, “nor” was used.

biological, step- or adopted children”.⁴

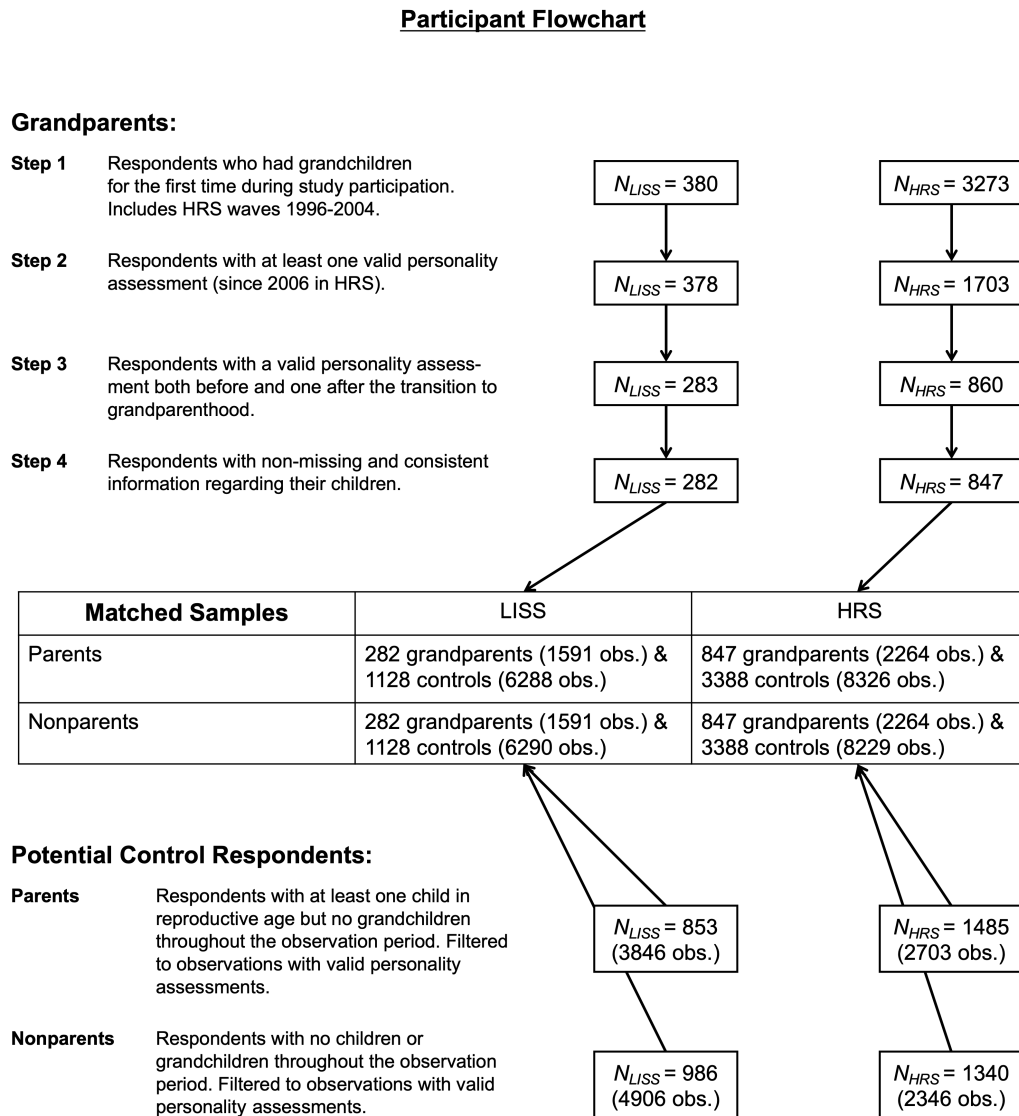

In both samples, we tracked grandparenthood status over time. Due to longitudinally inconsistent data in some cases, we included in the grandparent group only respondents with one transition from 0 (*no grandchildren*) to 1 (*at least one grandchild*) in this status variable, and no transitions backwards (see Figure 1). We marked respondents who consistently indicated that they had no grandchildren as potential members of the control groups.

Moderators

Based on insights from previous research, we tested three variables as potential moderators of the mean-level trajectories of the Big Five and life satisfaction over the transition to grandparenthood: First, we analyzed whether female gender (0 = *male*, 1 = *female*) acted as a moderator as indicated by research on life satisfaction (Di Gessa et al., 2019; Tanskanen et al., 2019).

Second, we tested whether performing paid work (0 = *no*, 1 = *yes*) was associated with divergent trajectories of the Big Five and life satisfaction (Schwaba & Bleidorn, 2019). Since the LISS subsample consisted solely of respondents performing paid work, we performed these analyses only in the HRS. This served two purposes. On the one hand, it allowed us to test how respondents in the workforce differed from those not working, which might shed light on role conflict and have implications for social investment mechanisms. On the other hand, these moderation analyses allowed us to assess whether potential differences in results between the LISS and HRS samples could be accounted for by including performing paid work as a moderator in HRS analyses. In other words, perhaps the results in the HRS respondents performing paid work were similar to those seen in the LISS sample, which had already been conditioned on this variable through filtering in the questionnaire.

⁴ The listing of biological, step-, or adopted children has been added since wave 2006.

**Figure 1**

Participant flowchart demonstrating the composition of the four analysis samples via matching (1:4 matching ratio with replacement). obs. = longitudinal observations.

Third, we examined how involvement in grandchild care moderated trajectories of the Big Five and life satisfaction (Arpino, Bordone, et al., 2018; Danielsbacka et al., 2019; Danielsbacka & Tanskanen, 2016). We coded a moderator variable (0 = *provided less than 100 hours of grandchild care*, 1 = *provided 100 or more hours of grandchild care*) based on the question “Did you (or your [late] husband / wife / partner) spend 100 or more hours in total since the last interview / in the last two years taking care of grand- or great grandchildren?”.⁵ This information was only available for grandparents in the HRS; in the LISS, too few respondents answered respective follow-up questions to be included in analyses.

Procedure

Drawing on all available data, three main restrictions defined the final analysis samples of grandparents (see Figure 1): First, we identified respondents who indicated having grandchildren for the first time during study participation ($N_{LISS} = 380$; $N_{HRS} = 3273$, including HRS waves 1996-2004 before personality assessments were introduced). Second, we restricted the sample to respondents with at least one valid personality assessment (valid in the sense that at least one of the six outcomes was non-missing; $N_{LISS} = 378$; $N_{HRS} = 1703$).⁶ Third, we included only respondents with both one valid personality assessment before and one after the transition to grandparenthood ($N_{LISS} = 283$; $N_{HRS} = 860$). Finally, a few respondents were excluded because of inconsistent or missing information regarding their children resulting in the final analysis samples of first-time grandparents, $N_{LISS} = 282$ (54.61% female; age at transition to grandparenthood $M = 58.29$, $SD = 4.87$) and $N_{HRS} = 847$ (54.90% female; age at transition to grandparenthood $M = 61.80$, $SD = 6.87$).

⁵ Dichotomization of a continuous construct (hours of care) is not ideal for moderation analysis (MacCallum et al., 2002). However, there were too many missing values in the variable assessing hours of care continuously (variables *E063).

⁶ We also excluded $N = 30$ HRS grandparents in a previous step who reported unrealistically high numbers of grandchildren (> 10) in their first assessment following the transition to grandparenthood.

We defined two pools of potential control subjects to be involved in the matching procedure: The first comprised parents who had at least one child of reproductive age (defined as $15 \leq age_{firstborn} \leq 65$) but no grandchildren during the observation period ($N_{LISS} = 853$ with 3846 longitudinal observations; $N_{HRS} = 1485$ with 2703 longitudinal observations). The second comprised respondents who reported being childless throughout the observation period ($N_{LISS} = 986$ with 4906 longitudinal observations; $N_{HRS} = 1340$ with 2346 longitudinal observations). The two control groups were, thus, by definition mutually exclusive.

Covariates

To match each grandparent with the control respondent from each pool of potential controls who was most similar in terms of the included covariates, we used propensity score matching.

Although critical to the design, covariate selection has seldom been explicitly discussed in studies estimating effects of life events (e.g., in matching designs). We see two (in part conflicting) traditions that address covariate selection: First, classic recommendations from psychology are to include all available variables that are associated with both the treatment assignment process (i.e., selection into treatment) and the outcome (e.g., Steiner et al., 2010; Stuart, 2010). Second, recommendations from a structural causal modeling perspective (Elwert & Winship, 2014; Rohrer, 2018) are more cautious, aiming to avoid pitfalls such as conditioning on a pre-treatment collider (collider bias) or a mediator (overcontrol bias). Structural causal modeling, however, requires advanced knowledge of the causal structures underlying the involved variables (Pearl, 2009).

In selecting covariates, we followed the guidelines of VanderWeele et al. (2019; 2020), which reconcile both views and offer practical guidance when the underlying causal structures are not completely understood and when using large archival datasets. The “modified disjunctive cause criterion” (VanderWeele, 2019, p. 218) recommends selecting

all available covariates which are assumed to be causes of the outcomes, treatment exposure (i.e., the transition to grandparenthood), or both, as well as any proxies for an unmeasured common cause of the outcomes and treatment exposure. Variables that are assumed to be instrumental variables (i.e., assumed causes of treatment exposure that are unrelated to the outcomes except through the exposure) and collider variables (Elwert & Winship, 2014) should be excluded from this selection. Because all covariates we used for matching were measured at least two years before the birth of the grandchild, we judge the risk of introducing collider bias or overcontrol bias to be relatively small. In addition, as mentioned above, the event of transition to grandparenthood is not planned by or under the direct control of the grandparents, which further reduces the risk of these biases.

Following these guidelines, we selected covariates covering respondents' demographics (e.g., age, education), economic situation (e.g., income), and health (e.g., mobility difficulties). We also included the pre-transition outcome variables as covariates—as recommended in the literature (Cook et al., 2020; Hallberg et al., 2018; Steiner et al., 2010; VanderWeele et al., 2020), as well as wave participation count and assessment year in order to control for instrumentation effects and historical trends (e.g., 2008/2009 financial crisis; Baird et al., 2010; Luhmann et al., 2014). To match grandparents with the parent control group, we additionally selected covariates containing information on fertility and family history (e.g., number of children, age of first three children) which were causally related to the timing of the transition to grandparenthood (Arpino, Gumà, et al., 2018; Margolis & Verdery, 2019).

An overview of all covariates we used to compute the propensity scores can be found in the supplemental materials (see Tables S5 & S6). Importantly, as part of our preregistration we also provided a justification for each covariate explaining whether we assumed it to be related to the treatment assignment, the outcomes, or both (see *gp-covariates-overview.xlsx* on https://osf.io/75a4r/?view_only=ac929a2c41fb4afd9d1a64a3909848d0). We tried to find

substantively equivalent covariates in both samples but had to compromise in a few cases (e.g., children’s educational level only in HRS vs. children living at home only in LISS).

Estimating propensity scores required complete covariate data. Therefore, we performed multiple imputations in order to account for missingness in our covariates (Greenland & Finkle, 1995). Using five imputed data sets computed by classification and regression trees (CART; Burgette & Reiter, 2010) in the *mice* R package (van Buuren & Groothuis-Oudshoorn, 2011), we predicted treatment assignment (i.e., the transition to grandparenthood) five times per observation in logistic regressions with a logit link function.⁷ We averaged these five scores per observation to compute the final propensity score to be used for matching (Mitra & Reiter, 2016). We used imputed data only for propensity score computation and not in later analyses because nonresponse in the outcome variables was negligible.

Propensity Score Matching

The time of matching preceded the survey year in which the transition to grandparenthood was first reported by at least two years (aside from that choosing the smallest available gap between matching and transition). This ensured that the covariates were not affected by the event itself or anticipation thereof (i.e., matching occurred well before children would have announced that they were expecting their first child; Greenland, 2003; Rosenbaum, 1984; VanderWeele et al., 2020). Propensity score matching was performed using the *MatchIt* R package (Ho et al., 2011) with exact matching on gender combined with Mahalanobis distance matching on the propensity score. Four matchings were performed; two per sample (LISS; HRS) and two per control group (parents; nonparents). We matched 1:4 with replacement because of the relatively small pools of available controls. This meant that each grandparent was matched with four control

⁷ In these logistic regressions, we included all covariates listed above as predictors except for *female*, which was later used for exact matching, and health-related covariates in LISS wave 2014, which were not assessed in that wave.

observations in each matching procedure, and that control observations were allowed to be used multiple times for matching.⁸ We did not specify a caliper because our goal was to find matches for all grandparents, and because we achieved good covariate balance this way.

We evaluated the matching procedure in terms of covariate balance and, graphically, in terms of overlap of the distributions of the propensity score (Stuart, 2010). Covariate balance as indicated by the standardized difference in means between the grandparent and the controls after matching was good (see Tables S5 & S6), lying below 0.25 as recommended in the literature (Stuart, 2010), and below 0.10 with few exceptions (Austin, 2011). Graphically, group differences in the distribution of propensity scores were small and indicated no substantial missing overlap (see Figure S1).

After matching, each matched control observation was assigned the same value as the matched grandparent in the *time* variable describing the temporal relation to treatment, and the control respondent's other longitudinal observations were centered around this matched observation. We thus coded a counterfactual transition time frame for each control respondent. Due to left- and right-censored longitudinal data (i.e., panel entry or attrition), we restricted the final analysis samples to six years before and six years after the transition, as shown in Table 1.

The final LISS analysis samples (see Figure 1) contained 282 grandparents with 1591 longitudinal observations, matched with 1128 control respondents with either 6288 (parent control group) or 6290 longitudinal observations (nonparent control group). The final HRS analysis samples contained 847 grandparents with 2264 longitudinal

⁸ In the LISS, 282 grandparent observations were matched with 1128 control observations; these control observations corresponded to 561 unique person-year observations stemming from 281 unique respondents for the parent control group, and to 523 unique person-year observations stemming from 194 unique respondents for the nonparent control group. In the HRS, 847 grandparent observations were matched with 3388 control observations; these control observations corresponded to 1363 unique person-year observations stemming from 978 unique respondents for the parent control group, and to 1039 unique person-year observations stemming from 712 unique respondents for the nonparent control group.

Note. obs. = observations. *time* = 0 marks the first year where the transition to grandparenthood has been reported. The number of grandparent respondents included in the final samples is $N_{LJSS} = 282$ and $N_{HRS} = 847$.

observations, matched with 3388 control respondents with either 8326 (parent control group) or 8229 longitudinal observations (nonparent control group). In the HRS, there were a few additional missing values in the outcomes ranging from 19 to 99 longitudinal observations, which were listwise deleted in the respective analyses.

Transparency and Openness

We used R (Version 4.0.4; R Core Team, 2021) and the R-packages *lme4* (Version 1.1.27.1; Bates et al., 2015), and *lmerTest* (Version 3.1.3; Kuznetsova et al., 2017) for multilevel modeling, as well as *tidyverse* (Wickham, Averick, Bryan, Chang, McGowan, François, et al., 2019) for data wrangling, and *papaja* (Aust & Barth, 2020) for reproducible manuscript production. A complete list of software we used is provided in the supplemental materials. The preregistration and scripts for data wrangling, analyses, and to reproduce this manuscript⁹ can be found on the OSF (https://osf.io/75a4r/?view_only=ac929a2c41fb4afd9d1a64a3909848d0) and on GitHub ([https://github.com/ \[blinded\]](https://github.com/[blinded])). LISS and HRS data are available online after registering accounts. Following Benjamin et al. (2018), we set the α -level for confirmatory analyses to .005.

Analytical Strategy

Our design can be referred to as an interrupted time series with a “nonequivalent no-treatment control group” (Shadish et al., 2002, p. 182) where treatment, that is, the transition to grandparenthood, is not deliberately manipulated. First, to analyze mean-level changes (research question 1), we used linear piecewise regression coefficients in multilevel models with person-year observations nested within respondents and households (Hoffman, 2015). To model change over time in relation to the transition to grandparenthood, we coded three piecewise regression coefficients: a *before-slope* representing linear change in the years leading up to the transition to grandparenthood, an

⁹ We also provide “*Instructions to Reproduce.pdf*” on the OSF.

554 *after-slope* representing linear change in the years after the transition, and a *shift*
 555 coefficient, shifting the intercept directly after the transition was first reported, thus
 556 representing sudden changes that go beyond changes already modeled by the *after-slope*
 557 (see Table 1 for the coding scheme of these coefficients).¹⁰ Other studies of personality
 558 development have recently adopted similar piecewise coefficients (e.g., Schwaba & Bleidorn,
 559 2019; Krämer & Rodgers, 2020; van Scheppingen & Leopold, 2020).

560 All effects of the transition to grandparenthood on the Big Five and life satisfaction
 561 were modeled as deviations from patterns in the matched control groups by interacting the
 562 three piecewise coefficients with the treatment variable (0 = *control*, 1 = *grandparent*). In
 563 additional models, we interacted these coefficients with the moderator variables, resulting
 564 in two- and three-way interactions. To test differences in the growth parameters between
 565 two groups in cases where these differences were represented by multiple fixed-effects
 566 coefficients, we defined linear contrasts using the *linearHypothesis* command from the *car*
 567 package (Fox & Weisberg, 2019). All models of mean-level changes were estimated using
 568 maximum likelihood and included random intercepts but no random slopes. We included
 569 the propensity score as a level-2 covariate for a double-robust approach (Austin, 2017).
 570 Model equations can be found in the supplemental materials.

571 Second, to assess interindividual differences in change (research question 2), we
 572 added random slopes to the models. In other words, we allowed for differences between
 573 individuals in their trajectories of change to be modeled, that is, differences in the
 574 *before-slope*, *after-slope*, and *shift* coefficients. Because multiple simultaneous random
 575 slopes are often not computationally feasible, we added random slopes one at a time and
 576 used likelihood ratio tests to determine whether the addition of the respective random

¹⁰ As an additional robustness check, we re-estimated the mean-level trajectories after further restricting the analysis time frame by excluding time points earlier than two years before the transition (i.e., before the latest time of matching). This served the purpose of assessing whether including time points from before matching (as preregistered) would distort the trajectories in any way. However, results were highly similar across all outcomes (see *gp_restricted_models.pdf* on https://osf.io/75a4r/?view_only=ac929a2c41fb4afd9d1a64a3909848d0).

slope led to a significant improvement in model fit. To statistically test differences in the random slope variance between the grandparent group and each control group, we respecified the models as heterogeneous variance models using the *nlme* R package (Pinheiro et al., 2021), which allowed for separate random slope variances to be estimated in the grandparent group and the control group within the same model. We compared the fit of these heterogeneous variance models to corresponding models with a homogeneous (single) random slope variance using likelihood ratio tests.

Third, to examine rank-order stability in the Big Five and life satisfaction over the transition to grandparenthood (research question 3), we computed the test-retest correlation of measurements prior to the transition to grandparenthood (at the time of matching) and the first available measurement afterwards. To test differences in test-retest correlations between grandparents and either of the control groups, we entered the pre-treatment measure, the treatment variable ($0 = \textit{control}$, $1 = \textit{grandparent}$), and their interaction into regression models predicting the Big Five and life satisfaction. The interaction tests for significant differences in the rank-order stability between those who experienced the transition to grandparenthood and those who did not (see Denissen et al., 2019; McCrae, 1993).

Results

Throughout the results section, we referred to statistical tests with $.005 < p < .05$ as *suggestive evidence* as stated in our preregistration.

Descriptive Results

Means and standard deviations of the Big Five and life satisfaction over the analyzed time points are presented in Tables S3 and S4. Visually represented (see Figures S2-S7), all six outcomes display marked stability over time in both LISS and HRS. Intra-class correlations (see Table S2) show that large portions of the total variance in the Big Five could be explained by nesting in respondents ($median = 0.75$), while nesting in

**Figure 2**

Unstandardized Effect Sizes of the Basic Models Across Analysis Samples (Regression Coefficients $\hat{\gamma}$ or Linear Contrasts $\hat{\gamma}_c$ From Multilevel Models, see Tables 2, S7, S13, S14, S19, S20, S27, S28, S35, S36, S43, S44). Error Bars Represent 95% Confidence Intervals.

households only accounted for minor portions of the total variance (ICC_{hid} , median = 0.03). For outcome-subsample combinations with ICC_{hid} below 0.05 we omitted the household nesting factor from all models to bypass computational errors—a small deviation from our preregistration. For life satisfaction, the nesting in households accounted for slightly larger portions of the total variance (median = 0.37) than nesting in respondents (median = 0.30). Across all outcomes, the proportion of variance due to within-person factors was relatively low (median = 0.23).

**Figure 3**

Unstandardized Effect Sizes of the Models Including the Gender Interaction Across Analysis Samples (Regression Coefficients $\hat{\gamma}$ or Linear Contrasts $\hat{\gamma}_c$ From Multilevel Models, see Tables 3, S8, S15, S16, S21, S22, S29, S30, S37, S38, S45, S46). Error Bars Represent 95% Confidence Intervals.

Mean-Level Changes

Figures 2 and 3 summarize the effects of the basic (i.e., unmoderated) models and those including the gender interaction for all outcomes and across the four analysis samples.

Agreeableness

In the basic models (see Tables 2 & S7 and Figure 4), we found no evidence that grandparents increased as compared to the controls (suggestive evidence in the LISS parent sample: $\hat{\gamma}_{21} = 0.01$, 95% CI [0.00, 0.02], $p = .030$). The models including the gender interaction (see Tables 3 & S8 and Figure 4) indicated that grandfathers slightly increased in agreeableness as compared to the parent controls (LISS: $\hat{\gamma}_{21} = 0.02$, 95% CI [0.01, 0.04], $p = .002$; suggestive evidence in the HRS: $\hat{\gamma}_{21} = 0.03$, 95% CI [0.01, 0.05], $p = .008$), whereas grandmothers did not differ from the female controls.

There was no consistent evidence for moderation by paid work (see Tables S9 & S10 and Figure S8) or by providing substantial grandchild care (see Tables S11 & S12 and Figure S9).

Note. Two models were computed for each of the two samples (LISS, HRS): grandparents matched with parent controls and with nonparent controls. CI = confidence interval.

626 *Conscientiousness*

627 We no differences between grandparents and both parent and nonparent controls in
 628 their trajectories of conscientiousness (see Tables S13 & S14 and Figure S10). There was
 629 only inconsistent evidence for a moderation by gender (see Tables S15 & S16 and Figure
 630 S10): Grandfathers' conscientiousness decreased immediately following the transition to
 631 grandparenthood as compared to male nonparents in the HRS, $[\hat{\gamma}_{21} + \hat{\gamma}_{31}] = -0.07$, 95% CI
 632 $[-0.11, -0.02]$, $p = .004$, but not in any of the other three analysis samples.

633 There were significant differences in conscientiousness depending on grandparents'
 634 work status (see Tables 5 & S17 and Figure 6): non-working grandparents saw more
 635 pronounced increases in conscientiousness in the years before the transition to
 636 grandparenthood compared to non-working parent, $\hat{\gamma}_{21} = 0.08$, 95% CI $[0.03, 0.13]$, $p <$
 637 $.001$, and nonparent controls, $\hat{\gamma}_{21} = 0.06$, 95% CI $[0.02, 0.11]$, $p = .004$, and compared to
 638 working grandparents (difference in *before* parameter; parents: $[\hat{\gamma}_{30} + \hat{\gamma}_{31}] = -0.08$, 95% CI
 639 $[-0.13, -0.03]$, $p = .002$; nonparents: $[\hat{\gamma}_{30} + \hat{\gamma}_{31}] = -0.08$, 95% CI $[-0.12, -0.03]$, $p = .001$).
 640 Grandparents providing substantial grandchild care increased in conscientiousness to a
 641 greater degree than the matched respondents (difference in *after* parameter; parents: $[\hat{\gamma}_{21}$
 642 $+ \hat{\gamma}_{31}] = 0.04$, 95% CI $[0.02, 0.06]$, $p < .001$; nonparents: $[\hat{\gamma}_{21} + \hat{\gamma}_{31}] = 0.04$, 95% CI $[0.02,$
 643 $0.06]$, $p < .001$; see Tables 4 & S18 and Figure 5). There was only suggestive evidence that
 644 grandparents who provided substantial grandchild care increased more strongly in
 645 conscientiousness after the transition compared to grandparents who did not (difference in
 646 *after* parameter; parents: $[\hat{\gamma}_{30} + \hat{\gamma}_{31}] = 0.03$, 95% CI $[0.00, 0.06]$, $p = .029$; nonparents: $[\hat{\gamma}_{30}$
 647 $+ \hat{\gamma}_{31}] = 0.03$, 95% CI $[0.01, 0.06]$, $p = .019$).

648 *Extraversion*

649 The trajectories of grandparents' extraversion closely followed those of the matched
 650 controls. There were no significant effects indicating differences between grandparents and
 651 controls in the basic models (see Tables S19 & S20 and Figure S11), the models including

LISS**HRS****Figure 4**

Change trajectories of agreeableness based on the basic models (left column) and the models including the gender interaction (right column). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The vertical line indicates the approximate time of the transition to grandparenthood.

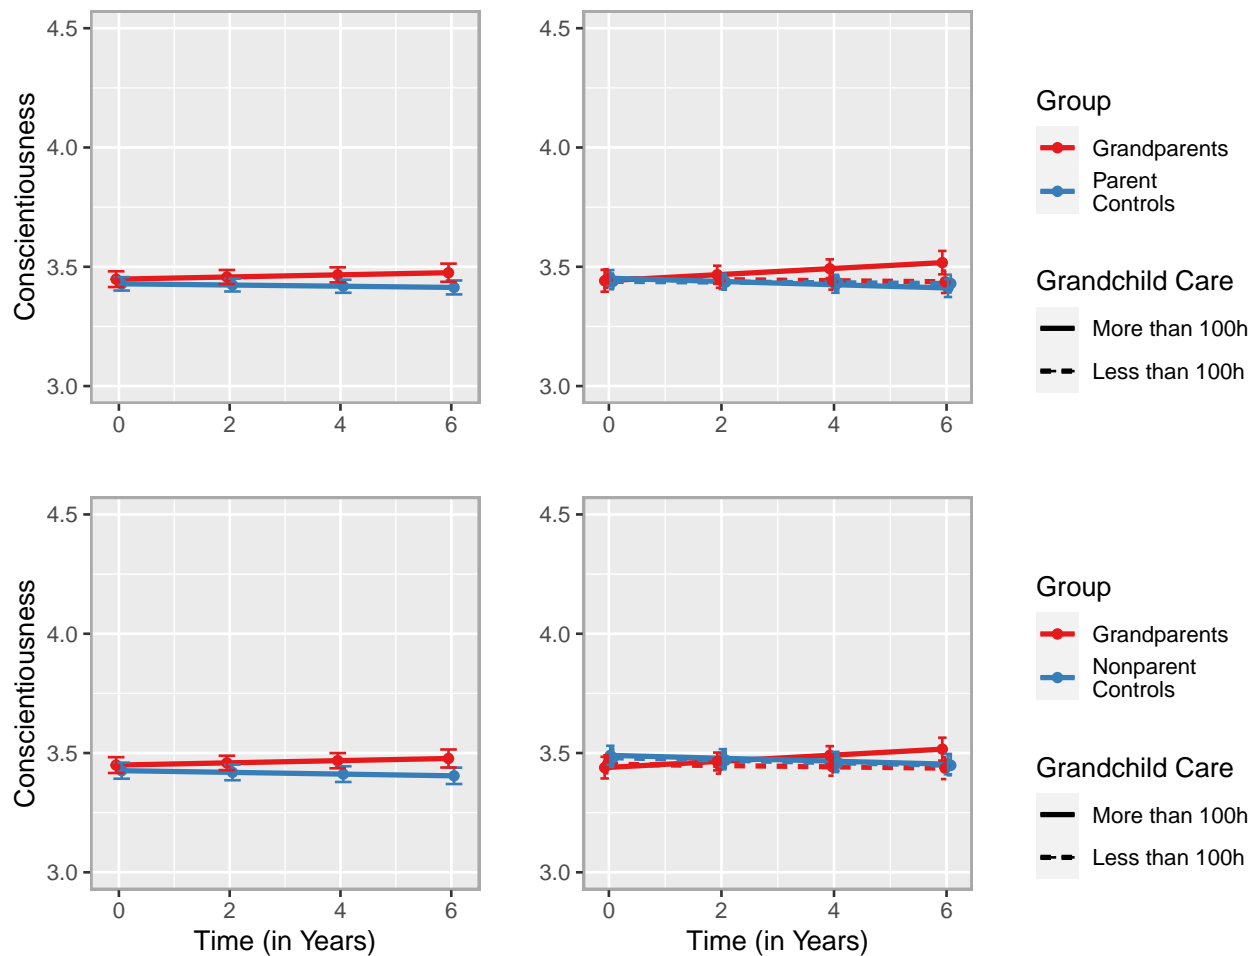

652 the gender interaction (see Tables S21 & S22 and Figure S11), the models of moderation by
653 paid work (see Tables S23 & S24 and Figure S12), or the models of moderation by
654 grandchild care (see Tables S25 & S26 and Figure S13).

HRS**Figure 6**

Change trajectories of conscientiousness based on the models of moderation by paid work (see Table 5). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The vertical line indicates the approximate time of the transition to grandparenthood. The plots in the left column are the same as in Figure S10 (basic models) and added here for better comparability.

Neuroticism

The basic models for neuroticism (see Tables S27 & S28 and Figure S14) showed only minor differences between grandparents and matched controls: Compared to HRS

parent controls, HRS grandparents shifted slightly downward in their neuroticism immediately after the transition to grandparenthood (difference in *shift* parameter: $[\hat{\gamma}_{21} + \hat{\gamma}_{31}] = -0.07$, 95% CI $[-0.11, -0.02]$, $p = .003$; suggestive evidence in the nonparent sample: $[\hat{\gamma}_{21} + \hat{\gamma}_{31}] = -0.05$, 95% CI $[-0.09, 0.00]$, $p = .042$), which was not the case in the LISS samples. The models including the gender interaction (see Tables S29 & S30 and Figure S14) showed one significant effect in the comparison of grandparents and controls: In the HRS, grandfathers, compared to male parent controls, shifted downward in neuroticism directly after the transition to grandparenthood (difference in *shift* parameter: $[\hat{\gamma}_{21} + \hat{\gamma}_{31}] = -0.15$, 95% CI $[-0.21, -0.08]$, $p < .001$). Thus, the effect present in the basic models seemed to be mostly due to differences in the grandfathers (vs. male controls).

Grandparents' trajectories of neuroticism as compared to the controls were significantly moderated by paid work in one instance (see Tables S31 & S32 and Figure S15): Compared to working controls, working grandparents increased more strongly in neuroticism in the years before the transition to grandparenthood (difference in *before* parameter; parents: $[\hat{\gamma}_{21} + \hat{\gamma}_{31}] = 0.06$, 95% CI $[0.02, 0.10]$, $p = .001$; nonparents: $[\hat{\gamma}_{21} + \hat{\gamma}_{31}] = 0.06$, 95% CI $[0.02, 0.09]$, $p = .002$). There was no evidence that grandparents providing substantial grandchild care differed in neuroticism from grandparents who did not (see Tables S33 & S34 and Figure S16).

Openness

For openness, we also found a high degree of similarity between grandparents and matched control respondents in their trajectories based on the basic models (see Tables S35 & S36 and Figure S17) and models including the gender interaction (see Tables S37 & S38 and Figure S17). Grandfathers in the HRS shifted downward in openness in the first assessment after the transition to grandparenthood to a greater extent than the male parent controls (difference in *shift* parameter: $[\hat{\gamma}_{21} + \hat{\gamma}_{31}] = -0.09$, 95% CI $[-0.14, -0.03]$, $p = .002$). However, this was not the case in the other three analysis samples.

The analysis of moderation by performing paid work revealed only one significant effect for openness trajectories (see Tables S39 & S40 and Figure S18): Non-working grandparents increased more strongly in openness post-transition than non-working parent controls ($\hat{\gamma}_{41} = 0.04$, 95% CI [0.02, 0.06], $p < .001$; suggestive evidence in the nonparent sample: $\hat{\gamma}_{41} = 0.03$, 95% CI [0.01, 0.05], $p = .015$). The analysis of moderation by grandchild care did not provide evidence for differences in openness between grandparents providing substantial grandchild care and those who did not (see Tables S41 & S42 and Figure S19).

Life Satisfaction

We found no consistent evidence that grandparents' life satisfaction trajectories differed significantly from those of the controls in either the basic models (see Tables S43 & S44 and Figure S20) or the models including the gender interaction (see Tables S45 & S46 and Figure S20). There was also no evidence of a moderation of life satisfaction by performing paid work (see Tables S47 & S48 and Figure S21) or grandchild care (see Tables S49 & S50 and Figure S22).

Interindividual Differences in Change

First, we conducted comparisons of model fit between the random intercept models reported previously and models where a random slope variance was estimated, separately for each change parameter. These comparisons showed a substantial amount of interindividual differences in change for all random slopes in all models, as indicated by increases in model fit significant at $p < .001$.

Second, we estimated models with heterogeneous random slope variances of the grandparents and each control group in order to test whether interindividual differences in change were significantly larger in the grandparents. Contrary to hypothesis H2, for agreeableness, conscientiousness, extraversion, and neuroticism, interindividual differences in intraindividual change were greater in the control group for all tested effects (see Tables

S51, S52, S53, & S54). In the two HRS samples, assuming group heterogeneity in the random slope variances led to significant improvements in model fit in all model comparisons. In the two LISS samples, this was the case for around half the tests.

For openness, interindividual differences in change before the transition to grandparenthood were significantly greater in the HRS grandparents than the nonparent controls (random slope variances of the *before* parameter), *likelihood ratio* = 57.57, $p < .001$. This result could not be replicated in the other three samples, and the other parameters of change either did not differ between groups in their random slope variances or had significantly larger random slope variances in the respective control group (see Table S55).

We found larger interindividual differences in grandparents' changes in life satisfaction before the transition to grandparenthood compared to the nonparent controls in the HRS (random slope variances of the *before* parameter), *likelihood ratio* = 115.87, $p < .001$ (see Table S56). This was not corroborated in the other three analysis sample and, overall, the majority of tests for heterogeneous random slope variances in life satisfaction indicated either non-significant differences or significantly larger random slope variances in the control sample.

Rank-Order Stability

As indicators of rank-order stability, we computed test-retest correlations for the Big Five and life satisfaction for the matched sample, and also separately for grandparents only and controls only (see Table 6). In 5 out of 24 comparisons grandparents' test-retest correlation was lower than that of the respective control group. However, differences in rank-order stability between grandparents and control respondents did not reach significance in any of these comparisons. Overall, we found no confirmatory evidence in support of hypothesis H3.¹¹

¹¹ In addition to the preregistered retest interval, we also computed a maximally large retest interval between the first available pre-transition assessment and the last available post-transition assessment

Discussion

In an analysis of first-time grandparents in comparison with both parent and nonparent matched control respondents, we found pronounced stability in the Big Five and life satisfaction over the transition to grandparenthood. Although there were a few isolated effects in line with our hypotheses on mean-level increases in agreeableness and conscientiousness, and decreases in neuroticism (H1a), they were very small in size and also not consistent over the two analyzed panel studies (LISS and HRS) or the two matched

within the observation period. Here, 3 out of 24 comparisons indicated that rank-order stability was lower in the grandparents. There was only one significant difference in rank-order stability in accordance with our hypothesis: HRS grandparents' rank-order stability in openness was lower than that of the nonparents, $p < .001$ (see Table S57). Another analysis also failed to provide convincing evidence that grandparents' rank-order stability was lower: We followed the preregistered approach but then excluded any duplicate control respondents resulting from matching with replacement who might bias results towards greater stability in the controls. Descriptively, 10 out of 24 comparisons showed lower rank-order stability in the grandparents compared to either control group (see Table S58). However, differences between groups were small and nonsignificant throughout.

Table 6
Rank-Order Stability.

Life Satisfaction	0.49	0.55	0.48	0.54	0.55	0.54

Note. Test-retest correlations as indicators of rank-order stability, and p-values indicating significant group differences therein between grandparents and each control group. The average retest intervals in years are 3.06 ($SD = 0.89$) for the LISS parent sample, 3.05 ($SD = 0.94$) for the LISS nonparent sample, 4.15 ($SD = 0.77$) for the HRS parent sample, and 4.11 ($SD = 0.67$) for the HRS nonparent sample. *Cor* = correlation; *GP* = grandparents; *con* = controls.

control groups (parents and nonparents). We found suggestive evidence that grandparents providing substantial grandchild care increased slightly more strongly in conscientiousness and decreased slightly more strongly in neuroticism than grandparents who did not (H1b), as well as partial evidence for moderation of mean-level trajectories of conscientiousness, neuroticism, and openness by performing paid work. There was no consistent evidence that grandmothers reached higher levels of life satisfaction following the transition to grandparenthood (H1c). Although interindividual differences in change were present for all parameters of change, they were only greater in the grandparents compared to the controls in a small minority of the model comparisons conducted (H2). Finally, rank-order stability did not differ between grandparents and either control group, or it was lower in the control group—contrary to expectations (H3).

Social Investment Principle

We conducted a preregistered, cross-study, and multi-comparison test of the social investment principle (Lodi-Smith & Roberts, 2007; Roberts & Wood, 2006) in middle adulthood and old age, which posits that the transition to grandparenthood is a potentially important developmental task driving development of the Big Five personality traits (Hutteman et al., 2014). Across all analyzed traits, we found more evidence of trait stability than of change.

Still, whereas we did not find *consistent* evidence of personality development across the transition to grandparenthood, the direction of the (sparse) effects we found generally supported the social investment principle—in contrast to development following parenthood (Asselmann & Specht, 2020b; van Scheppingen et al., 2016). Below, we summarize our findings in support of the social investment principle because even small psychological effects may be meaningful and involve real-world consequences (Götz et al., 2021). For agreeableness and conscientiousness we found slight post-transition increases in comparison to the matched control groups that were in line with the social investment

principle. However, the effects were not only small but also inconsistent across samples. Agreeableness only increased in the LISS (compared to parents) and conscientiousness only in the HRS (compared to both parents and nonparents). In the HRS, neuroticism decreased in grandparents directly following the transition to grandparenthood when compared to matched parent respondents. This was not the case in the LISS or compared to HRS nonparents.

In the case of agreeableness and neuroticism, these effects were only present in the comparison of grandfathers and male controls, whereas no effects were found for grandmothers. In contrast, past research—mostly in the domains of well-being and health—found more pronounced effects of the transition to grandparenthood for grandmothers (Di Gessa et al., 2016b, 2019; Sheppard & Monden, 2019; Tanskanen et al., 2019). This has been discussed in the context of grandmothers spending more time with their grandchildren than grandfathers and providing more hours of care (Condon et al., 2013; Di Gessa et al., 2020), thus making a higher social investment.¹² We found partial support for this for life satisfaction (see below). Yet our results for the Big Five were not in agreement with this line of thought. One possible explanation is that (future) grandfathers were previously more invested in their work lives than in child rearing, and at the end of their career or after retirement, found investments in grandchild care to be a more novel and meaningful transition than grandmothers (StGeorge & Fletcher, 2014; Tanskanen et al., 2021). Currently, however, empirical research specifically on the grandfather role is sparse (for a qualitative approach, see Mann & Leeson, 2010), while the demography of grandparenthood is undergoing sweeping changes, with rising proportions of grandfathers actively involved in grandchild care (see Coall et al., 2016; Mann, 2007). Thus, more research into grandfathers' experience of the transition to grandparenthood is needed to substantiate our tentative findings.

¹² In the HRS analysis sample, the proportion of grandparents reporting that they have provided at least 100 hours of grandchild care since the last assessment was also slightly higher in grandmothers ($M = 0.45$, $SD = 0.50$) than grandfathers ($M = 0.41$, $SD = 0.49$).

To gain more insight into social investment mechanisms, we tested paid work and grandchild care as moderators. For conscientiousness, we found that grandparents who were not gainfully employed increased more strongly in anticipation of the transition to grandparenthood than working grandparents (and than the matched nonworking controls). Although this could imply that working grandparents did not find as much time for social investment because of the role conflict with the employee/worker role (see Tanskanen et al., 2021), we would have expected these moderation effects after the transition, when grandparents were indeed able to spend time with their grandchild. However, such post-transition differences did not surface. Results for neuroticism were even less clearly in line with the social investment principle: Working grandparents increased in neuroticism in anticipation of the transition to grandparenthood (compared to nonparents), and decreased immediately following the transition (compared to parents). Regarding moderation by grandchild care, our results suggested that grandparents who provided substantial grandchild care increased more in conscientiousness and decreased more in neuroticism compared to grandparents who did not. However, the strength of the evidence was weak and indicates a need for temporally more fine-grained assessments with more extensive instruments of grandchild care (e.g., Vermote et al., 2021; see also Fingerman et al., 2020).

In total, evidence in favor of the social investment principle in our analyses was rather thin. This adds to other recent empirical tests in the context of parenthood and romantic relationships (Asselmann & Specht, 2020a, 2020b; Spikic et al., 2021; van Scheppingen et al., 2016) that have challenged the original core assumption of personality maturation through age-graded social role transitions. It now seems likely that distinct (or additional) theoretical assumptions and mechanisms are required to explain empirical findings of personality development in middle adulthood and old age. First steps in that direction include the recent distinction between social investment and divestment (Schwaba & Bleidorn, 2019) in the context of retirement (for the related distinction between personality maturation and relaxation, see Asselmann & Specht, 2021), as well as the

hypothesis that personality development is more closely tied to the subjective perceptions of adult role competency than to the transitions per se (Roberts & Davis, 2016).

Nonetheless, the possibility remains that preconditions we have not considered have to be met for grandparents to undergo personality development after the transition to grandparenthood. For example, grandparents might need to live in close proximity to their grandchild, see them on a regular basis, and provide grandchild care above a certain quantity and quality (e.g., level of responsibility). To our knowledge, however, there are presently no datasets with such detailed information regarding the grandparent role in conjunction with multiple waves of Big Five personality data. Studies in the well-being literature have provided initial evidence that more frequent contact with grandchildren was associated with higher grandparental well-being (Arpino, Bordone, et al., 2018; Danielsbacka et al., 2019; Danielsbacka & Tanskanen, 2016). However, Danielsbacka et al. (2019) noted that this effect was due to between-person differences in grandparents, thus limiting a causal interpretation of frequency of grandchild care as a mechanism of development in psychological characteristics like life satisfaction and personality.

Life Satisfaction

Similar to our findings on the Big Five personality traits, we did not find convincing evidence that life satisfaction changed as a consequence of the transition to grandparenthood. Only in the LISS in comparison with the nonparent control group did grandparents' life satisfaction increase slightly at the first assessment following the transition to grandparenthood. This difference was present in grandmothers but not grandfathers. While this pattern of effects is in line with several studies reporting increases associated with women becoming grandmothers (e.g., Di Gessa et al., 2019; Tanskanen et al., 2019), we did not uncover it reliably in both samples or with both comparison groups and also did not see consistent effects in the linear trajectories after the transition to grandparenthood. As mentioned in the introduction, a study of the effects of the transition

on first-time grandparents' life satisfaction that used fixed effects regressions also did not discover any positive within-person effects of the transition (Sheppard & Monden, 2019). Further, in line with this study, we did not find evidence that grandparents who provided substantial grandchild care increased more strongly in life satisfaction than those who did not, and grandparents' life satisfaction trajectories were also not moderated by employment status (Sheppard & Monden, 2019).

Overall, evidence has accumulated that there is an association between having grandchildren and higher life satisfaction on the between-person level—especially for (maternal) grandmothers who provide frequent grandchild care (Danielsbacka et al., 2011; Danielsbacka & Tanskanen, 2016)—but no within-person effect of the transition. The main reason for this divergence is the presence of *selection* effects, that is, confounding which we have accounted for through the propensity score matching design, but which was present in previous within-person estimates of change (Luhmann et al., 2014; Thoemmes & Kim, 2011; VanderWeele et al., 2020).

Interindividual Differences in Change

Analyzing how grandparents differed interindividually in their trajectories of change provided additional insight beyond the analysis of mean-level change. All parameters of change exhibited considerable interindividual differences. Similar to Denissen et al. (2019), who found significant model fit improvements of random slopes in most models (see also Doré & Bolger, 2018), this pattern indicates that respondents—both grandparents and matched controls—deviated to a considerable extent from the average trajectories that we reported on previously.

We expected larger interindividual differences in grandparents because life events differ in their impact on daily life and in the degree to which they are perceived as meaningful or emotionally significant (Doré & Bolger, 2018; Luhmann et al., 2020). Our results, however, indicated that interindividual differences were larger in the controls than

the grandparents for many models, or not significantly different between groups. Only in a small minority of tests were interindividual differences significantly larger in grandparents (concerning the linear slope in anticipation of grandparenthood for neuroticism, openness, and life satisfaction). Overall, we did not find evidence supporting the hypothesis that interindividual differences in change would be larger in the grandparents than the controls (H2).

When integrating this result into the literature, it is important to keep in mind that most previous studies did not compare interindividual differences in personality change between the event group and a comparison group (even if they did use comparison groups for the main analyses; Denissen et al., 2019; Schwaba & Bleidorn, 2019; cf. Jackson & Beck, 2021). As demonstrated by an analysis across the entire life span (i.e., irrespective of life events; Schwaba & Bleidorn, 2018), interindividual differences in personality change—although largest in emerging adulthood—were substantial up until around 70 years of age in most domains. Regarding the substantive question of how the transition to grandparenthood affects interindividual differences in change, we therefore propose that it is more informative to test grandparents' degree of variability in change against well-matched control groups than against no groups as often done previously.

Recently, Jackson and Beck (2021) presented evidence that the experience of sixteen commonly analyzed life events was mostly associated with decreases in interindividual variation in the Big Five compared to those not experiencing the respective event. They used a comparable approach to ours but in a SEM latent growth curve framework and not accounting for covariates related to pre-existing group differences (i.e., without matching). Their results based on the German SOEP data suggested—contrary to their expectations—that most life events made people *more* similar to each other (Jackson & Beck, 2021). Thus, taken together with our results, it seems that the assumption that life events and transitions ostensibly produce increased heterogeneity between people needs to be scrutinized in future studies.

Rank-Order Stability

We also investigated whether grandparents' rank-order stability in the Big Five personality traits and life satisfaction over the transition to grandparenthood was lower than that of the matched controls. Conceptually, rank-order changes are possible in the absence of mean-level changes. Empirically, though, we did not find evidence supporting our hypothesis (H3): Rank-order stability did not differ significantly between grandparents and controls and, descriptively, was larger in the grandparents in the majority of comparisons. In a recent study of the effects of eight different life events on the development of the Big Five personality traits and life satisfaction (Denissen et al., 2019), comparably high rank-order stability was reported in the event groups. Only particularly adverse events such as widowhood and disability significantly lowered respondents' rank-order stability (Chopik, 2018; Denissen et al., 2019).

Regarding the Big Five's general age trajectories of rank-order stability, support for inverted U-shape trajectories was recently strengthened in a study of two panel data sets (Seifert et al., 2021). This study also explored that health deterioration accounted for parts of the decline of personality stability in old age. Therefore, it is possible that in later developmental phases (see also Hutteman et al., 2014) rank-order stability of personality is largely influenced by health status and less by normative life events. In the context of grandparenthood, this relates to research into health benefits (Chung & Park, 2018; Condon et al., 2018; Di Gessa et al., 2016a, 2016b; cf. Ates, 2017) and decreases to mortality risk associated with grandparenthood or grandchild care (Choi, 2020; Christiansen, 2014; Hilbrand et al., 2017; cf. Ellwardt et al., 2021). Grandparenthood might therefore have a time-lagged effect on personality stability through protective effects on health. However, with the currently available data, such a mediating effect cannot be reliably recovered (under realistic assumptions; Rohrer et al., 2021).

Limitations and Future Directions

The current study has a number of strengths that bolster the robustness of its inferences: It features a preregistered analysis of archival data with an internal cross-study replication, a propensity score matching design that carefully deliberated covariate choice, and a twofold comparison of all effects of the grandparents against matched parents (with children of reproductive age) and nonparents. To obtain a comprehensive picture of personality development, we analyzed mean-level changes, interindividual differences in change, and changes in rank-order stability. Both of the panel studies we used had their strengths and weaknesses: The HRS had a larger sample of first-time grandparents besides information on important moderators, but it assessed personality and life satisfaction only every four years. The LISS assessed the outcomes every year (apart from a few waves with planned missingness) but restricted the grandparent sample through filtering of the relevant questions to employed respondents, resulting in a smaller and younger sample. Together, the strengths of one dataset partially compensated for the limitations of the other.

Still, a number of limitations need to be addressed: First, there remains some doubt whether we were able to follow truly socially invested grandparents over time. More detailed information regarding a grandparent's relationship with their first and later grandchildren and the level of care a grandparent provides would be a valuable source of information on social investment, as would information on possible constraining factors such as length and cost of travel between grandparent and grandchild. Lacking such precise contextual information, the multidimensionality of the grandparent role (Buchanan & Rotkirch, 2018; Findler et al., 2013; Thiele & Whelan, 2006) might lend itself to future investigations into grandparents' personality development using growth mixture models (Grimm & Ram, 2009; Infurna, 2021; Ram & Grimm, 2009). On a similar note, we did not consider grandparents' subjective perception of the transition to grandparenthood in terms of the emotional significance, meaningfulness, and impact on daily lives, which might be responsible for differential individual change trajectories (Haehner et al., 2021; Kritzler et

al., 2021; Luhmann et al., 2020).

Second, we relied on self-report personality data and did not include other-reports by family members or close friends (Luan et al., 2017; McCrae, 2018; McCrae & Mõttus, 2019; Mõttus et al., 2019; Schwaba et al., 2022). Thus, our results might be influenced by common method bias (Podsakoff et al., 2003). Large-scale panel data incorporating both self- and other-reports of personality over time would be needed to address this issue (e.g., Oltmanns et al., 2020).

Third, a causal interpretation of our results rests on a number of assumptions that are not directly testable with the data (Li, 2013; Stuart, 2010): Most importantly, we assumed that we picked the right sets of covariates, that our model to estimate the propensity score was correctly specified, and that there was no substantial remaining bias due to unmeasured confounding. Working with archival data meant that we had no influence on data collection, and we also aimed for roughly equivalent sets of covariates across both data sets. Therefore, we had to make some compromises on covariate choice. Still, we believe that our procedure to select covariates following state-of-the-art recommendations (see *Methods*; VanderWeele et al., 2020), and to substantiate each covariate's selection explicitly within our preregistration improved upon previously applied practices. Regarding the propensity score estimation, we opted to estimate the grandparents' propensity scores at a specific time point at least two years before the transition to grandparenthood, which had the advantages that (1) the covariates were uncontaminated by anticipation of the transition, and (2) the matched controls had a clear counterfactual timeline of transition (for similar recent approaches analyzing life events, see Balbo & Arpino, 2016; Krämer & Rodgers, 2020; van Scheppingen & Leopold, 2020). Regarding the timing of measurements and the transition to grandparenthood, it also has to be emphasized that we might have missed more short-term effects playing out over months instead of years.

Fourth, our results only pertain to the countries for which our data are

representative on a population level: the Netherlands and the United States. Personality development, and more specifically personality maturation, have been examined cross-culturally (e.g., Bleidorn et al., 2013; Chopik & Kitayama, 2018). On the one hand, these studies showed universal average patterns of change towards greater maturity over the life span. On the other hand, they emphasized cultural differences regarding norms and values and the temporal onset of social roles. For grandparenthood, there are substantial demographic differences between countries (Leopold & Skopek, 2015), as well as differences in public child care systems that may demand different levels of grandparental involvement (Bordone et al., 2017; Hank & Buber, 2009). In the Netherlands, people become grandparents six years later on average than in the United States (Leopold & Skopek, 2015). Furthermore, although both countries have largely market-based systems for early child care, parents in the Netherlands on average have access to more extensive childcare services through (capped) governmental benefits (OECD, 2020). Despite these differences, our results from the Dutch and US samples did not indicate systematic discrepancies.

Finally, while we assessed our dependent variables using highly reliable scales, there was a conceptual difference in the Big Five measures (see John & Srivastava, 1999) in the two studies: The IPIP Big Five inventory used in the LISS (Goldberg, 1992) presented statements as items, and asked respondents to indicate how accurately these statements described them (using a bipolar response scale). However, the Midlife Development Inventory used in the HRS (Lachman & Weaver, 1997) presented adjectives as items, and asked respondents how well these adjectives described them (using a unipolar response scale). This discrepancy hindered the between-sample comparison somewhat and also resulted in different distributions of the Big Five across samples (see Figures S2-S7). The possibility should also be pointed out that our analyses on the domain-level of the Big Five could be too conceptually broad to identify patterns of personality development over the transition to grandparenthood that are discernible on the level of facets or nuances (Möttus & Rozgonjuk, 2021; Schwaba et al., 2022).

Conclusion

Do personality traits change over the transition to grandparenthood? Using data from two nationally representative panel studies in a preregistered propensity score matching design, the current study revealed that trajectories of the Big Five personality traits and life satisfaction remained predominantly stable in first-time grandparents over this transition compared to matched parents and nonparents. We found slight post-transition increases to grandparents' agreeableness and conscientiousness in line with our hypothesis of personality development based on the social investment principle. However, these effects were minuscule and inconsistent across analysis samples. In addition, our analyses revealed (1) a lack of consistent moderation of personality development by grandparents providing substantial grandchild care, (2) interindividual differences in change that were mostly smaller in grandparents than in matched respondents, and (3) comparable rank-order stability in grandparents and matched respondents. Thus, we conclude that the transition to grandparenthood did not act as a straightforwardly important developmental task driving personality development in middle adulthood and old age (as previously proposed, see Hutteman et al., 2014). With more detailed assessment of the grandparent role, future research could investigate whether personality development occurs in a subset of grandparents who are highly socially invested.

Supplemental Material

Model Equations

Model equation for the basic (i.e., unmoderated) models (ignoring the additional nesting in households applied to the majority of models):

$$\begin{aligned}
 y_{ti} &= \beta_{0i} + \beta_{1i}before_{ti} + \beta_{2i}after_{ti} + \beta_{3i}shift_{ti} + e_{ti} \\
 \beta_{0i} &= \gamma_{00} + \gamma_{01}grandparent_i + \gamma_{02}pscore_i + v_{0i} \\
 \beta_{1i} &= \gamma_{10} + \gamma_{11}grandparent_i \\
 \beta_{2i} &= \gamma_{20} + \gamma_{21}grandparent_i \\
 \beta_{3i} &= \gamma_{30} + \gamma_{31}grandparent_i ,
 \end{aligned} \tag{A1}$$

where at time t for person i $e_{ti} \sim N(0, \sigma_e^2)$ and $v_{0i} \sim N(0, \tau_{00})$. y_{ti} represented one of the Big Five or life satisfaction. Separate models were computed for LISS and HRS samples, and for parent and nonparent matched controls.

Model equation for the models including the gender interaction (moderator variable $female_i$):

$$\begin{aligned}
 y_{ti} &= \beta_{0i} + \beta_{1i}before_{ti} + \beta_{2i}after_{ti} + \beta_{3i}shift_{ti} + e_{ti} \\
 \beta_{0i} &= \gamma_{00} + \gamma_{01}grandparent_i + \gamma_{02}female_i + \gamma_{03}grandparent_i female_i \\
 &\quad + \gamma_{04}pscore_i + v_{0i} \\
 \beta_{1i} &= \gamma_{10} + \gamma_{11}grandparent_i + \gamma_{12}female_i + \gamma_{13}grandparent_i female_i \\
 \beta_{2i} &= \gamma_{20} + \gamma_{21}grandparent_i + \gamma_{22}female_i + \gamma_{23}grandparent_i female_i \\
 \beta_{3i} &= \gamma_{30} + \gamma_{31}grandparent_i + \gamma_{32}female_i + \gamma_{33}grandparent_i female_i ,
 \end{aligned} \tag{A2}$$

where $e_{ti} \sim N(0, \sigma_e^2)$ and $v_{0i} \sim N(0, \tau_{00})$. Again, we estimated separate models for each sample (LISS, HRS) and each comparison group (parents, nonparents).

1676 Model equation for the models including the interaction by paid work (moderator
1677 variable $working_{ti}$):

$$\begin{aligned}
 y_{ti} = & \beta_{0i} + \beta_{1i}working_{ti} + \beta_{2i}before_{ti} + \beta_{3i}before_{ti}working_{ti} + \beta_{4i}after_{ti} \\
 & + \beta_{5i}after_{ti}working_{ti} + \beta_{6i}shift_{ti} + \beta_{7i}shift_{ti}working_{ti} + e_{ti} \\
 \beta_{0i} = & \gamma_{00} + \gamma_{01}grandparent_i + \gamma_{02}pscore_i + v_{0i} \\
 \beta_{1i} = & \gamma_{10} + \gamma_{11}grandparent_i \\
 \beta_{2i} = & \gamma_{20} + \gamma_{21}grandparent_i \\
 \beta_{3i} = & \gamma_{30} + \gamma_{31}grandparent_i \\
 \beta_{4i} = & \gamma_{40} + \gamma_{41}grandparent_i \\
 \beta_{5i} = & \gamma_{50} + \gamma_{51}grandparent_i \\
 \beta_{6i} = & \gamma_{60} + \gamma_{61}grandparent_i \\
 \beta_{7i} = & \gamma_{70} + \gamma_{71}grandparent_i ,
 \end{aligned} \tag{A3}$$

1678 where $e_{ti} \sim N(0, \sigma_e^2)$ and $v_{0i} \sim N(0, \tau_{00})$. We estimated separate models for each
1679 comparison group (parents, nonparents) in the HRS.

1680 Model equation for the models including the interaction by grandchild care
1681 (moderator variable $caring_{ti}$):

$$\begin{aligned}
 y_{ti} = & \beta_{0i} + \beta_{1i}caring_{ti} + \beta_{2i}after_{ti} + \beta_{3i}after_{ti}caring_{ti} + e_{ti} \\
 \beta_{0i} = & \gamma_{00} + \gamma_{01}grandparent_i + \gamma_{02}pscore_i + v_{0i} \\
 \beta_{1i} = & \gamma_{10} + \gamma_{11}grandparent_i \\
 \beta_{2i} = & \gamma_{20} + \gamma_{21}grandparent_i \\
 \beta_{3i} = & \gamma_{30} + \gamma_{31}grandparent_i ,
 \end{aligned} \tag{A4}$$

1682 where $e_{ti} \sim N(0, \sigma_e^2)$ and $v_{0i} \sim N(0, \tau_{00})$. Restricted to the HRS post-transition period, we
1683 estimated separate models for each comparison group (parents, nonparents).

1684 **Supplemental Tables****Table S1***Internal Consistency Measures in the Four Analysis Samples at the Time of Matching.*

	A	C	E	N	O	LS
LISS: Parent controls						
ω_t	0.88	0.83	0.88	0.91	0.88	0.93
ω_h	0.75	0.57	0.71	0.72	0.63	0.78
α	0.83	0.78	0.84	0.87	0.78	0.91
LISS: Nonparent controls						
ω_t	0.89	0.88	0.93	0.92	0.88	0.89
ω_h	0.73	0.68	0.79	0.79	0.66	0.75
α	0.81	0.79	0.90	0.90	0.79	0.88
HRS: Parent controls						
ω_t	0.78	0.82	0.80	0.76	0.86	0.93
ω_h	0.67	0.48	0.68	0.59	0.61	0.88
α	0.78	0.59	0.75	0.71	0.77	0.90
HRS: Nonparent controls						
ω_t	0.84	0.77	0.81	0.76	0.85	0.92
ω_h	0.64	0.63	0.71	0.62	0.65	0.82
α	0.80	0.57	0.77	0.72	0.79	0.90

Note. A = agreeableness, C = conscientiousness, E = extraversion, N = neuroticism, O = openness, LS = life satisfaction. Omega total, ω_t , is based on “omega.tot” from the *psych::omega()* function, and omega hierarchical, ω_h , on “omega_h” (Revelle, 2021). For the LISS, we based the number of lower-order factors specified in “nfactors” on information supplied in Goldberg (1999). For the HRS, we could not find comparable information and used the default value. α is based on “raw_alpha” from the *psych::alpha()* function (Revelle, 2021).

Table S2*Intra-Class Correlations of Grandparents and Matched Controls in the Four Analysis Samples.*

	A	C	E	N	O	LS
LISS: Parent controls						
ICC_{pid}	0.76	0.76	0.83	0.67	0.76	0.28
ICC_{hid}	0.04	0.02	0.01	0.10	0.03	0.40
$ICC_{pid/hid}$	0.80	0.78	0.84	0.78	0.79	0.68
LISS: Nonparent controls						
ICC_{pid}	0.75	0.74	0.85	0.65	0.80	0.31
ICC_{hid}	0.00	0.01	0.00	0.10	0.01	0.34
$ICC_{pid/hid}$	0.75	0.75	0.85	0.74	0.81	0.65
HRS: Parent controls						
ICC_{pid}	0.75	0.73	0.76	0.71	0.58	0.28
ICC_{hid}	0.01	0.03	0.02	0.03	0.20	0.38
$ICC_{pid/hid}$	0.76	0.76	0.79	0.74	0.78	0.66
HRS: Nonparent controls						
ICC_{pid}	0.69	0.74	0.75	0.74	0.60	0.33
ICC_{hid}	0.08	0.05	0.04	0.01	0.22	0.37
$ICC_{pid/hid}$	0.77	0.79	0.80	0.75	0.83	0.70

Note. A = agreeableness, C = conscientiousness, E = extraversion, N = neuroticism, O = openness, LS = life satisfaction. Intra-class correlations are the proportion of total variation that is explained by the respective nesting factor. ICC_{pid} is the proportion of total variance explained by nesting in respondents which corresponds to the correlation between two randomly selected observations from the same respondent. ICC_{hid} is the proportion of total variance explained by nesting in households which corresponds to the correlation between two randomly selected observations from the same household. $ICC_{pid/hid}$ is the proportion of total variance explained by nesting in respondents and in households which corresponds to the correlation between two randomly selected observations from the same respondent and the same household.

open	Openness	cp*024 - cp*069	0.03	0.13	-0.16	0.00
participation	Waves participated	/	-0.71	-0.07	-0.18	-0.04
year	Year of assessment	wave	-0.63	-0.02	-0.16	-0.02

Note. PSM = propensity score matching, ref. = reference category, f. = female, m. = male, NA = covariate not used in this sample. The standardized difference in means between the grandparent and the two control groups (parent and nonparent) was computed by $(\bar{x}_{gp} - \bar{x}_c)/(\hat{\sigma}_{gp})$. Rules of thumb say that this measure should ideally be below .25 (Stuart, 2010) or below .10 (Austin, 2011).

Table S6

Standardized Difference in Means for Covariates Used in Propensity Score Matching and the Propensity Score in the HRS.

Note. PSM = propensity score matching, ref. = reference category, f. = female, m. = male, NA = covariate not used in this sample. The standardized difference in means between the grandparent and the two control groups (parent and nonparent) was computed by $(\bar{x}_{gp} - \bar{x}_c)/(\hat{\sigma}_{gp})$. Rules of thumb say that this measure should ideally be below .25 (Stuart, 2010) or below .10 (Austin, 2011).

Table S7

Linear Contrasts for Agreeableness.

Linear Contrast	Parent controls		Nonparent controls			
	$\hat{\gamma}_c$	χ^2	$\hat{\gamma}_c$	χ^2	p	
LISS						
Shift of the controls vs. 0 ($\hat{\gamma}_{20} + \hat{\gamma}_{30}$)	0.00	0.07	.792	0.00	0.01	.932
Shift of the grandparents vs. 0 ($\hat{\gamma}_{20} + \hat{\gamma}_{30} + \hat{\gamma}_{21} + \hat{\gamma}_{31}$)	0.02	0.90	.343	0.02	0.63	.428
Shift of the controls vs. shift of the grandparents ($\hat{\gamma}_{21} + \hat{\gamma}_{31}$)	0.02	0.52	.471	0.02	0.44	.506
Before-slope of the grandparents vs. 0 ($\hat{\gamma}_{10} + \hat{\gamma}_{11}$)	-0.01	2.75	.097	-0.01	2.02	.155
After-slope of the grandparents vs. 0 ($\hat{\gamma}_{20} + \hat{\gamma}_{21}$)	0.00	0.10	.748	0.00	0.12	.726
HRS						
Shift of the controls vs. 0 ($\hat{\gamma}_{20} + \hat{\gamma}_{30}$)	0.00	0.06	.806	0.01	2.86	.091
Shift of the grandparents vs. 0 ($\hat{\gamma}_{20} + \hat{\gamma}_{30} + \hat{\gamma}_{21} + \hat{\gamma}_{31}$)	0.00	0.02	.890	0.00	0.02	.896
Shift of the controls vs. shift of the grandparents ($\hat{\gamma}_{21} + \hat{\gamma}_{31}$)	0.00	0.05	.815	-0.01	0.42	.517
Before-slope of the grandparents vs. 0 ($\hat{\gamma}_{10} + \hat{\gamma}_{11}$)	0.00	0.09	.759	0.00	0.10	.746
After-slope of the grandparents vs. 0 ($\hat{\gamma}_{20} + \hat{\gamma}_{21}$)	0.00	0.27	.607	0.00	0.30	.581

Note. The linear contrasts are needed in cases where estimates of interest are represented by multiple fixed-effects coefficients and are computed using the *linearHypothesis* function from the *car* R package (Fox & Weisberg, 2019) based on the models from Table 2. $\hat{\gamma}_c$ = combined fixed-effects estimate.

Table S8

Linear Contrasts for Agreeableness (Moderated by Gender).

Linear Contrast	Parent controls			Nonparent controls		
	$\hat{\gamma}_c$	χ^2	p	$\hat{\gamma}_c$	χ^2	p

Neuroticism	0.70	0.76	0.68	0.68	0.76	0.65
Openness	0.74	0.79	0.73	0.78	0.79	0.78
Life Satisfaction	0.67	0.54	0.70	0.51	0.54	0.51
HRS						
Agreeableness	0.67	0.68	0.67	0.69	0.68	0.69
Conscientiousness	0.66	0.68	0.66	0.65	0.68	0.64
Extraversion	0.70	0.73	0.69	0.69	0.73	0.68
Neuroticism	0.64	0.67	0.64	0.63	0.67	0.62
Openness	0.70	0.71	0.70	0.76	0.71	0.77
Life Satisfaction	0.51	0.54	0.50	0.48	0.54	0.46

Note. Test-retest correlations as indicators of rank-order stability, and p-values indicating significant group differences therein between grandparents and each control group. The average retest intervals in years are 8.45 ($SD = 2.24$) for the LISS parent sample, 8.31 ($SD = 2.28$) for the LISS nonparent sample, 6.91 ($SD = 2.21$) for the HRS parent sample, and 6.96 ($SD = 2.27$) for the HRS nonparent sample. *Cor* = correlation; *GP* = grandparents; *con* = controls.

Table S58

Rank-Order Stability Excluding Duplicate Control Observations.

Outcome	Parent controls				Nonparent controls			
	<i>Cor_{all}</i>	<i>Cor_{GP}</i>	<i>Cor_{con}</i>	<i>p</i>	<i>Cor_{all}</i>	<i>Cor_{GP}</i>	<i>Cor_{con}</i>	<i>p</i>
LISS								
Agreeableness	0.79	0.81	0.77	.410	0.77	0.81	0.71	.007
Conscientiousness	0.80	0.80	0.79	.428	0.78	0.80	0.75	.395
Extraversion	0.86	0.87	0.85	.751	0.86	0.87	0.86	.709
Neuroticism	0.77	0.77	0.78	.925	0.76	0.77	0.75	.545
Openness	0.76	0.80	0.72	.111	0.81	0.80	0.82	.826
Life Satisfaction	0.65	0.66	0.63	.853	0.64	0.66	0.63	.252
HRS								
Agreeableness	0.69	0.70	0.68	.990	0.70	0.70	0.70	.943
Conscientiousness	0.70	0.69	0.70	.219	0.69	0.69	0.70	.513
Extraversion	0.74	0.75	0.73	.228	0.75	0.75	0.74	.159
Neuroticism	0.68	0.71	0.66	.599	0.72	0.71	0.74	.028
Openness	0.73	0.73	0.74	.887	0.74	0.73	0.76	.639
Life Satisfaction	0.56	0.55	0.57	.515	0.58	0.55	0.62	.031

Note. Test-retest correlations as indicators of rank-order stability, and p-values indicating significant group differences therein between grandparents and each control group. The average retest intervals in years are 2.90 ($SD = 0.90$) for the LISS parent sample, 2.90 ($SD = 0.92$) for the LISS nonparent sample, 3.91 ($SD = 0.96$) for the HRS parent sample, and 3.89 ($SD = 0.94$) for the HRS nonparent sample. *Cor* = correlation; *GP* = grandparents; *con* = controls.

Violin Plots for Agreeableness Including Means Over Time and LOESS Line.

LISS**HRS****Figure S3**

Violin Plots for Conscientiousness Including Means Over Time and LOESS Line.

LISS**HRS****Figure S4**

Violin Plots for Extraversion Including Means Over Time and LOESS Line.

LISS**HRS****Figure S5**

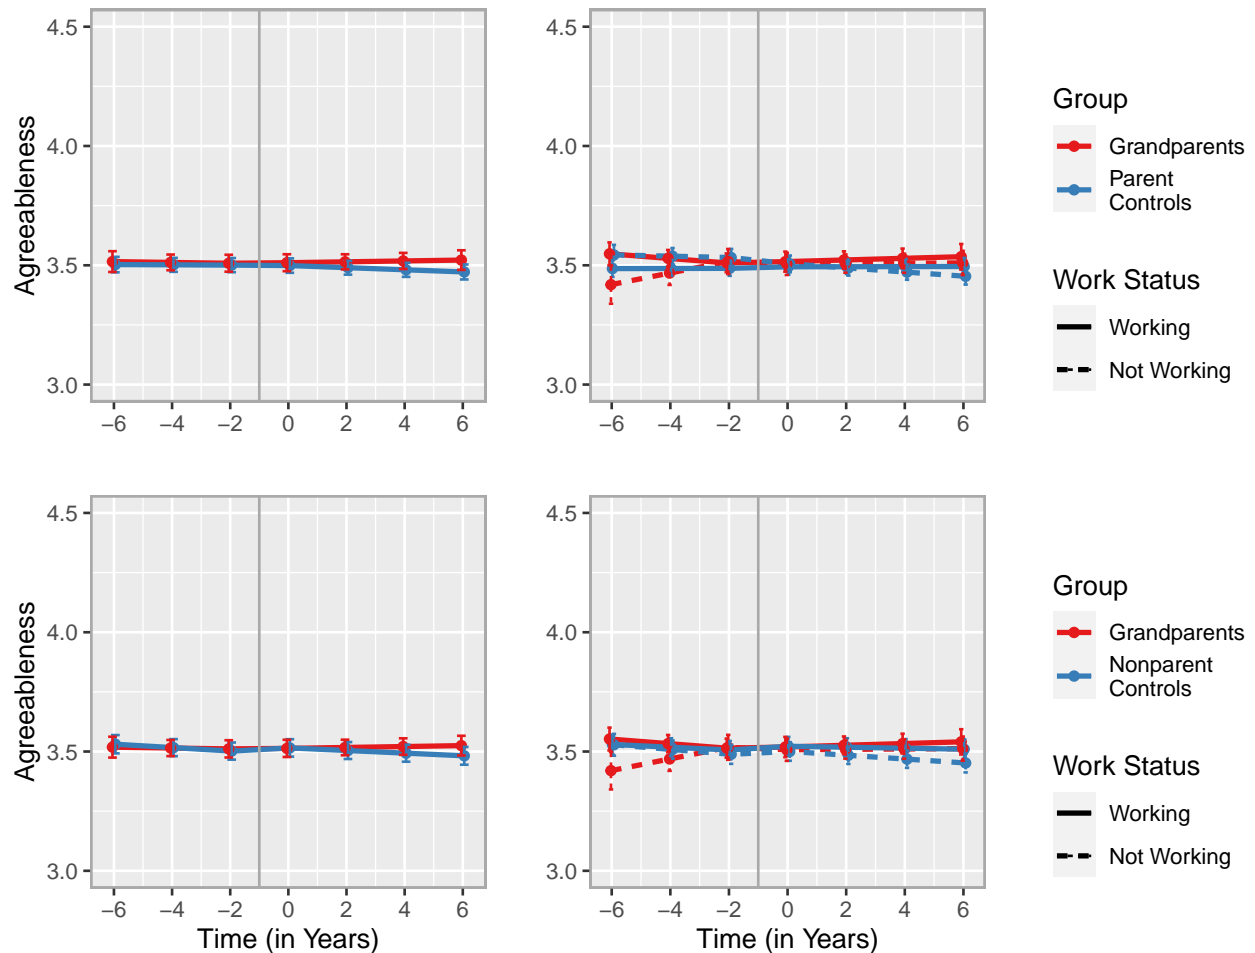

Violin Plots for Neuroticism Including Means Over Time and LOESS Line.

LISS**HRS****Figure S6**

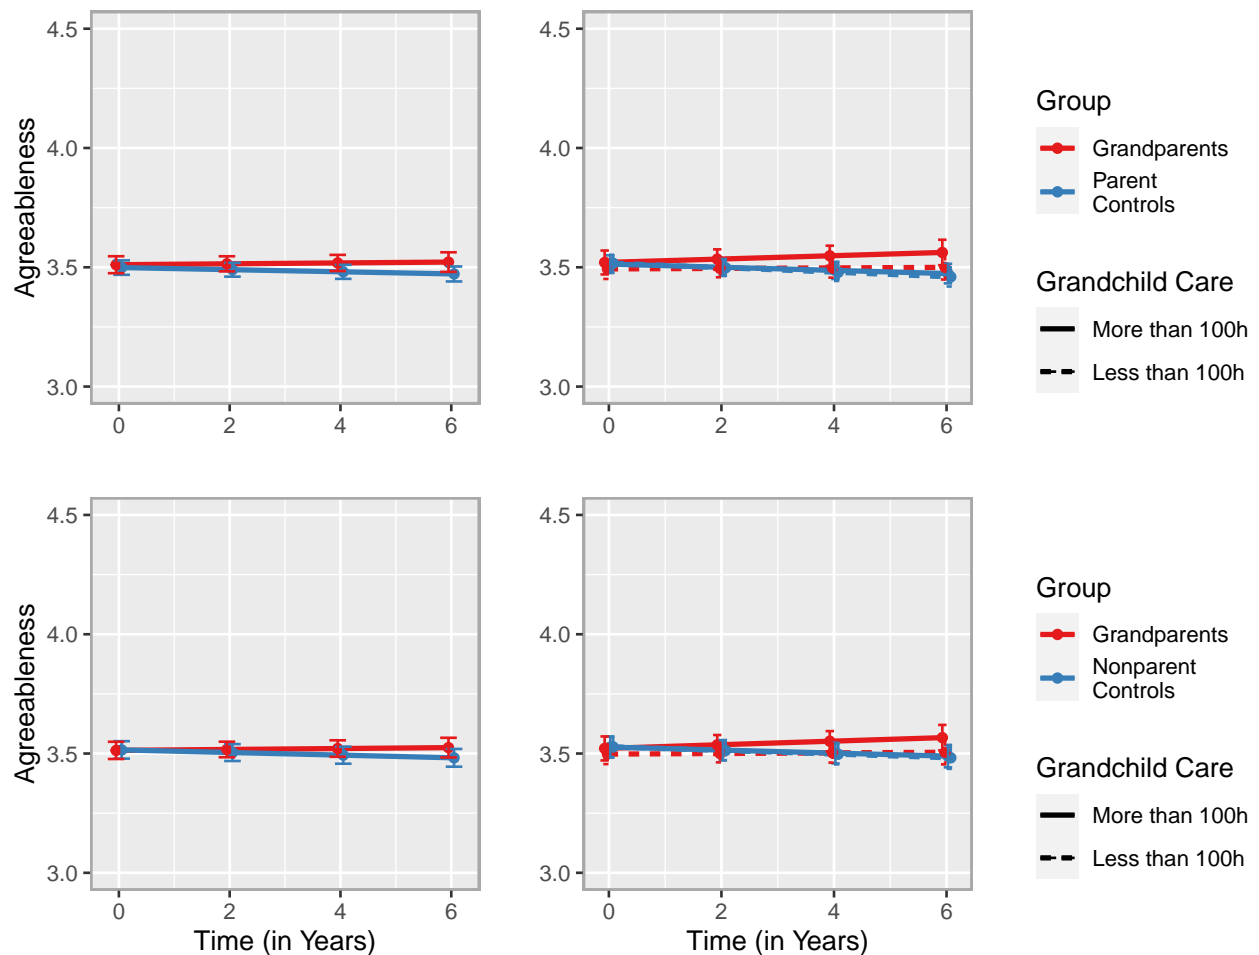

Violin Plots for Openness Including Means Over Time and LOESS Line.

LISS**HRS****Figure S7**

Violin Plots for Life Satisfaction Including Means Over Time and LOESS Line.

HRS**Figure S8**

Change trajectories of agreeableness based on the models of moderation by paid work (see Table S9). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The vertical line indicates the approximate time of the transition to grandparenthood. The plots in the left column are the same as in Figure 4 (basic models) and added here for better comparability.

HRS**Figure S9**

Change trajectories of agreeableness based on the models of moderation by grandchild care (see Table S11). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The plots in the left column are the same as in Figure 4 (basic models) but restricted to the post-transition period for better comparability.

LISS**HRS****Figure S10**

Change trajectories of conscientiousness based on the basic models (left column) and the models including the gender interaction (right column). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The vertical line indicates the approximate time of the transition to grandparenthood.

LISS**HRS****Figure S11**

Change trajectories of extraversion based on the basic models (left column) and the models including the gender interaction (right column). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The vertical line indicates the approximate time of the transition to grandparenthood.

HRS**Figure S12**

Change trajectories of extraversion based on the models of moderation by paid work (see Table S23). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The vertical line indicates the approximate time of the transition to grandparenthood. The plots in the left column are the same as in Figure S11 (basic models) and added here for better comparability.

HRS**Figure S13**

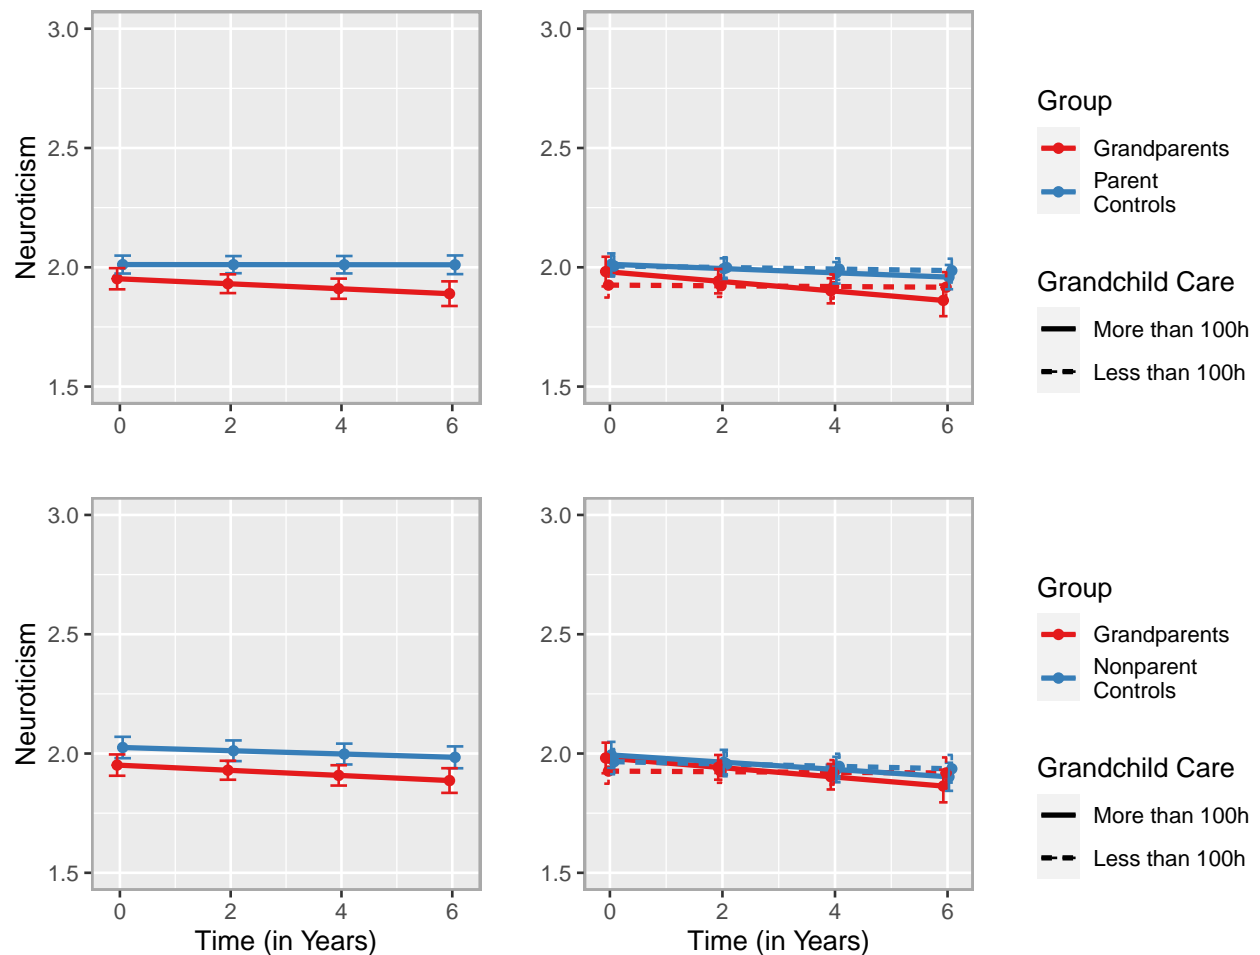

Change trajectories of extraversion based on the models of moderation by grandchild care (see Table S25). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The plots in the left column are the same as in Figure S11 (basic models) but restricted to the post-transition period for better comparability.

LISS**HRS****Figure S14**

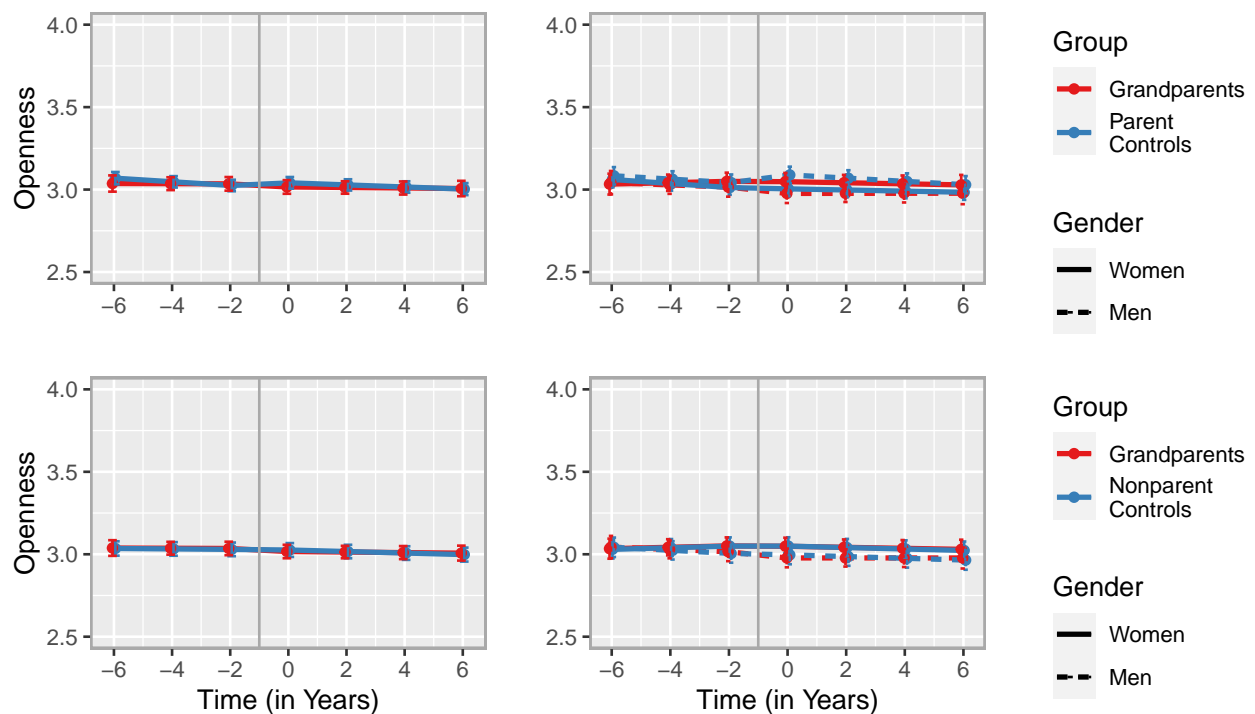

Change trajectories of neuroticism based on the basic models (left column) and the models including the gender interaction (right column). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The vertical line indicates the approximate time of the transition to grandparenthood.

HRS**Figure S15**

Change trajectories of neuroticism based on the models of moderation by paid work (see Table S31). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The vertical line indicates the approximate time of the transition to grandparenthood. The plots in the left column are the same as in Figure S14 (basic models) and added here for better comparability.

HRS**Figure S16**

Change trajectories of neuroticism based on the models of moderation by grandchild care (see Table S33). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The plots in the left column are the same as in Figure S14 (basic models) but restricted to the post-transition period for better comparability.

LISS**HRS****Figure S17**

Change trajectories of openness based on the basic models (left column) and the models including the gender interaction (right column). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The vertical line indicates the approximate time of the transition to grandparenthood.

HRS**Figure S18**

Change trajectories of openness based on the models of moderation by paid work (see Table S39). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The vertical line indicates the approximate time of the transition to grandparenthood. The plots in the left column are the same as in Figure S17 (basic models) and added here for better comparability.

HRS**Figure S19**

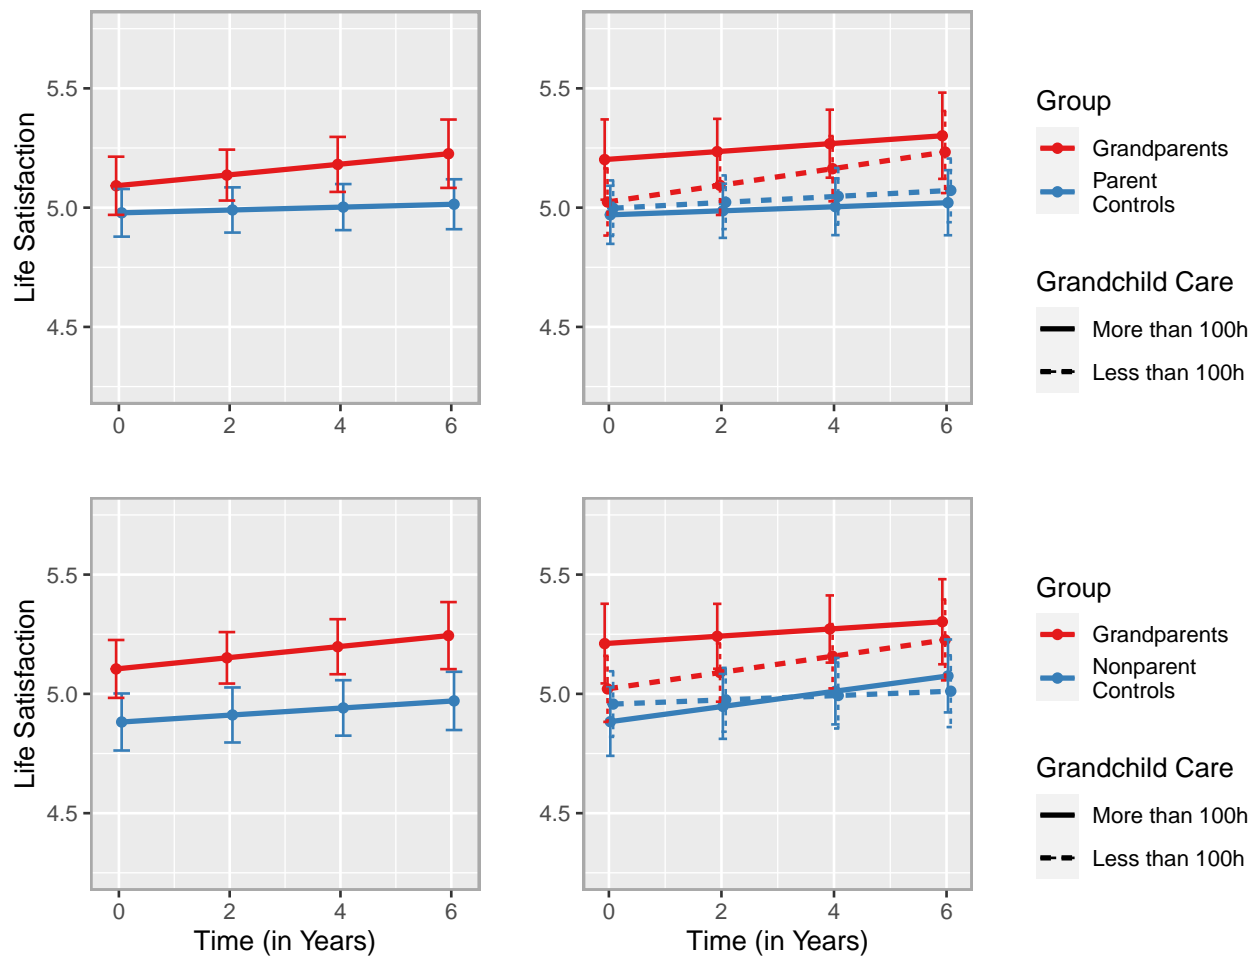

Change trajectories of openness based on the models of moderation by grandchild care (see Table S41). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The plots in the left column are the same as in Figure S17 (basic models) but restricted to the post-transition period for better comparability.

LISS**HRS****Figure S20**

Change trajectories of life satisfaction based on the basic models (left column) and the models including the gender interaction (right column). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The vertical line indicates the approximate time of the transition to grandparenthood.

HRS**Figure S21**

Change trajectories of life satisfaction based on the models of moderation by paid work (see Table S47). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The vertical line indicates the approximate time of the transition to grandparenthood. The plots in the left column are the same as in Figure S20 (basic models) and added here for better comparability.

HRS**Figure S22**

Change trajectories of life satisfaction based on the models of moderation by grandchild care (see Table S49). The error bars are 95% confidence intervals of the predicted values, which only account for the fixed-effects portion of the model. The plots in the left column are the same as in Figure S20 (basic models) but restricted to the post-transition period for better comparability.

Complete Software and Session Information

We used R (Version 4.0.4; R Core Team, 2021) and the R-packages *car* (Version 3.0.12; Fox et al., 2020a, 2020b), *carData* (Version 3.0.4; Fox et al., 2020b), *citr* (Version 0.3.2; Aust, 2019), *cowplot* (Version 1.1.1; Wilke, 2020), *dplyr* (Version 1.0.7; Wickham, François, et al., 2021), *forcats* (Version 0.5.1; Wickham, 2021a), *Formula* (Version 1.2.4; Zeileis & Croissant, 2010), *ggplot2* (Version 3.3.5; Wickham, 2016), *GPArotation* (Version 2014.11.1; Bernaards & I.Jennrich, 2005), *Hmisc* (Version 4.6.0; Harrell Jr, 2021), *lattice* (Version 0.20.41; Sarkar, 2008), *lme4* (Version 1.1.27.1; Bates et al., 2015), *lmerTest* (Version 3.1.3; Kuznetsova et al., 2017), *magick* (Version 2.7.3; Ooms, 2021), *MASS* (Version 7.3.53; Venables & Ripley, 2002), *Matrix* (Version 1.3.2; Bates & Maechler, 2021), *multcomp* (Version 1.4.18; Hothorn et al., 2008), *mvtnorm* (Version 1.1.1; Genz & Bretz, 2009), *nlme* (Version 3.1.152; Pinheiro et al., 2021), *papaja* (Version 0.1.0.9997; Aust & Barth, 2020), *png* (Version 0.1.7; Urbanek, 2013), *psych* (Version 2.1.9; Revelle, 2021), *purrr* (Version 0.3.4; Henry & Wickham, 2020), *readr* (Version 2.1.1; Wickham, Hester, et al., 2021), *scales* (Version 1.1.1; Wickham & Seidel, 2020), *stringr* (Version 1.4.0; Wickham, 2019), *survival* (Version 3.2.7; Terry M. Therneau & Patricia M. Grambsch, 2000), *TH.data* (Version 1.0.10; Hothorn, 2019), *tibble* (Version 3.1.6; Müller & Wickham, 2021), *tidyr* (Version 1.1.4; Wickham, 2021b), *tidyverse* (Version 1.3.1; Wickham, Averick, Bryan, Chang, McGowan, François, et al., 2019), and *tinylabels* (Version 0.2.2; Barth, 2021) for data wrangling, analyses, and plots. We used *renv* to create a reproducible environment for this R-project (Version 0.15.2; Ushey, 2022).

The following is the output of R's *sessionInfo()* command, which shows information to aid analytic reproducibility of the analyses.
